The first printed books on mathematics were a commercial arithmetic that appeared in 1478 and a Latin edition of Euclid’s *Elements* that appeared in 1482. Of greater mathematical significance was the publication in 1494 of *Summa de Arithmetica*, by Luca Pacioli. This book was written in Italian and was a complete summary of all arithmetic, algebra, and trigonometry known at that time.

Robert Recorde (ca. 1510–1558), called “the father of English mathematics,” published four books on mathematics, written in English: *The Ground of Artes*, an arithmetic; *The Castle of Knowledge*, the first English exposition of the Copernican theory in astronomy; *The Pathwaie to Knowledge*, an abridged version of Euclid’s *Elements*; and *The Whetstone of Witte*, an algebra, in which the equality sign “=” appears for the first time.

The Seventeenth Century

As part of the scientific explosion of the seventeenth century, mathematics experienced a period of growth unparalleled until modern times. The practical demands of society, the spread of education, and the general intellectual climate of the time contributed to this growth. The number of people engaged in mathematical activity became so large that only a few of the outstanding creative mathematicians and their major works can be mentioned.

John Napier (1550–1617), the Scottish contemporary of Galileo, published *Mirifici Logarithmorum Canonis Descriptio* (1614), in which he set forth the theory of logarithms.

Rene Descartes (1596–1650), the philosopher-scientist, sought to demonstrate that all scientific investigations are related and the key to that relation is mathematics. One of the appendixes to his famous *Discourse on Method* (1537), entitled “La Geometrie,” was the first publication of analytic geometry. In it, Descartes applied methods of algebra to geometry, enabling him to settle some previously insoluble classical problems.

Pierre de Fermat (1601–1665) is credited with inventing analytic geometry independently of Descartes,

with conceiving the tangential approach to differential calculus before either Newton or Leibniz were born, and with being one of the creators of the mathematical theory of probability. He is probably best known, however, for his work in number theory. Fermat published only a few papers; most of his results are known through letters he wrote to friends and from notes he made in margins of books.

Much of the work of Gerard Desargues (1593–1662) was eclipsed during his lifetime by Descartes' writings. But two centuries after his death his treatise on conics, *Brouillon project d'une atteinte aux événements des rencontres du cône avec un plan* (1639), was republished and he is considered the founder of modern projective geometry.

Another Frenchman, Blaise Pascal (1623–1662), did work in geometry (*Essay on Conics*, 1640) and also was the cocreator with Fermat of probability theory.

One of the most significant contributions of the seventeenth century was the invention of differential and integral calculus, which led to the development of analysis, one of the three major branches of mathematics. (Algebra and geometry are the other two.) Calculus may be characterized as the gateway between elementary and advanced mathematics; a knowledge of calculus is essential to any real understanding of physics and related branches of technology and a prerequisite to the study of analysis. As is the case so often in mathematical creativity, calculus was developed independently in England by Isaac Newton (1642–1727) and in Germany by Gottfried Wilhelm von Leibniz (1646–1716). This fact engendered one of the most bitter partisan feuds in mathematical history, with admirers of each man hurling charges of plagiarism at the other.

Newton's first publication involving his calculus was his famous *Philosophiae Naturalis Principia Mathematica*, 1687 (*The Mathematical Principles of Natural Philosophy*). His later monographs on the subject are: *De Analysis per Aequationes Numero Terminorum Infinitas*, 1669 (*An Analysis by Means of Equations with an Indefinite Number of Terms*); *Methodus Fluxionum et Serierum Infinitarum*, 1671 (*Method of Fluxions and Infinite Series*); and *Tractatus de Quadratura Curvarum*, 1676 (*Quadrature of Curves*).

Leibniz's results, as well as the development of his ideas, are contained in hundreds of pages of notes made from 1673 on, but never published by him. In 1684 he began publishing a few papers on calculus in the journal *Acta Eruditorum* and in 1714 he wrote *Historia et Origo Calculi Differentialis*, in which he gave an account of the development of his own thinking on the subject.

In addition to the expansion of mathematical content and activity, this period is significant for developments that occurred with respect to communication among mathematicians. Prior to the late sixteenth century, mathematics was created by individuals and small

groups headed by one or two prominent leaders. The results were communicated orally, through personal correspondence, and occasionally written up in texts—first in manuscript form and later as printed books. As more people began to participate in mathematical research, the desire for exchange of information and for the stimulus of meeting others with the same intellectual interests resulted in the founding of scientific societies. These societies were important not only in making possible direct contact and exchange of ideas, but also because they supported journals, which eventually became the accepted medium for publication of new research results. The oldest mathematical society still in existence is the Mathematische Gesellschaft in Hamburg, Germany, founded in 1690 as the *Kunstrechnungsliebende Societät*, and continued (1790–1876) as the *Gesellschaft zur Verbreitung der Mathematischen Wissenschaften*. Its publications were entitled *Jahresbriefe* or *Jahres-Berichte* or *Berichte* from 1723 to 1878 and its current journal is entitled *Mitteilungen*, 1873–.^[4]

Another seventeenth century development was the establishment of Royal Academies, subsidized by the rulers of the time. These academies sponsored research and also supported journals, in which they published the results of their research.

Eighteenth Century

Calculus dominated mathematical development in the eighteenth century. Research in this new theory took two directions: extension and application of calculus to other parts of mathematics and to physics, and examination of its logical foundations.

Research during this century was carried on mainly by the Royal Academies. The most prominent academies were at Berlin, London, Paris, and St. Petersburg. Prior to 1800, universities played only a minor role in research and the great mathematicians were attached to the academies.

Leonhard Euler (1707–1783), who was attached to both the Berlin Academy and the St. Petersburg Academy during his career, was the most productive mathematician of the century. He wrote about 900 books and papers, including works on mechanics, music, and astronomy, as well as mathematics. Euler is considered the creator of analytic mechanics (as opposed to the older geometrical mechanics), based on his achievements in establishing calculus as a purely analytic theory. His *Mechanica* (1736) is a major contribution to the analytical foundation of mechanics. Euler's texts on mechanics, algebra, mathematical analysis, analytic and differential geometry, and calculus of variations were standard works for a 100 years or more. Three landmark texts in calculus are: *Introductio in Analysin Infinitorum* (1748), the first connected

presentation of calculus and elementary analysis; *Institutiones Calculi Differentialis* (1755); and the three-volume *Institutiones Calculi Integralis* (1768–1770).

French mathematics held a position of superiority during the eighteenth century and some of the important works from that country are: *Traité de dynamique* (1743) and *Reflexions sur la cause générale des vents* (1747), by Jean d'Alembert; *Mécanique analytique* (1788) and *Théorie des fonctions analytiques* (1797), by Joseph Louis Lagrange; *Eléments de géométrie* (1794) and *Essai de la théorie des nombres* (1798), by Adrien-Marie Legendre; and *Feuilles d'analyse appliquée à la géométrie* (1795), by Gaspard Monge. An important work which, like its author, bridges two centuries, is the five-volume *Mécanique céleste* (1799–1825), by Pierre Simon Laplace. This work reviewed, unified, and greatly extended all previous work of Newton, d'Alembert, Euler, Lagrange, and Laplace, himself, in the fields of probability and celestial mechanics.

1800 to 1940

The modern area in mathematics is considered to have begun with Carl Friedrich Gauss (1777–1855), the German mathematician who dominated nineteenth century mathematics. He contributed to almost every branch of mathematics, but is perhaps best known for his work in the theory of numbers, represented by his monumental *Disquisitiones Arithmeticae* (1801).

With the beginning of the century, mathematical creativity began to increase exponentially, and by 1900 had produced about five times as much original mathematics as had been accomplished in all previous ages.^[1] Every major branch of mathematics underwent profound changes in terms of expansion of subject matter and the opening of new fields as well as the extension of older ones. Consequently, mathematics became so vast a subject that mathematicians were forced to confine their efforts to one major branch: algebra, geometry, or analysis. It has been said that Gauss was one of the last men to know the subject as a whole.

Algebra, which previously was little more than generalized arithmetic, was liberated from its dependence on arithmetic and became abstract, with wider applications, during this period. Early work in this area was done by the Irish mathematician William Rowan Hamilton (1805–1865) and the German mathematician Hermann Grassmann (1809–1877). Important works of Hamilton are *Lectures on Quaternions* (1853) and *Elements of Quaternions* (1866), and of Grassman, *Die Lineale Ausdehnungslehre* (1844). England was the center of this nineteenth-century algebra with its geometric applications under the guidance of Arthur Cayley (1821–1895), the originator of matrix theory, and James Joseph Sylvester (1814–1897). Cayley's writings are found in his *Collected Mathematical Papers*, 13 volumes, Cambridge University

Press, 1889–1897. Sylvester, who taught at Johns Hopkins University from 1876 until his return to England in 1884, published in various journals. He is also important for having initiated research in pure mathematics in the United States and for founding the first American mathematics journal, the *American Journal of Mathematics*. Also in the field of algebra, work was done in the theory of groups, notably by Felix Klein (1849–1925) in Germany, and by Marius Sophus Lie (1842–1899) in Norway. Both men published widely in journals and Klein also wrote books on the theory, history, and teaching of mathematics. Two of his books are *Famous Problems of Elementary Geometry* (1895; English translation 1930), and *Elementary Mathematics from an Advanced Standpoint* (2 vols., 1907–1908; English translation 1932–1940). Another man working in algebra at this time was the French mathematician Évariste Galois. One of the more romantic figures in mathematics history, Galois was killed in a duel in 1832, shortly before his twenty-first birthday. His unpublished notes, that were later deciphered and revised, turned out to be the theory of groups, the foundation of modern algebra and modern geometry.^[1]

In the field of analysis, three men are acknowledged to be the founders of the theory of complex functions: Augustin Louis Cauchy (France, 1789–1857), Bernhard Riemann (Germany, 1826–1866), and Karl Weierstrass (Germany, 1815–1897). Cauchy was a prolific writer, whose over 700 papers covered all branches of mathematics. His first significant paper in complex function theory was “Mémoire sur la théorie des intégrales définies,” read to the Paris Academy in 1814. The paper considered his most important was “Mémoire sur les intégrales définies prises entre des limites imaginaires,” written in 1825 but not published until 1874. Riemann's doctoral thesis of 1851, “Grundlagen für eine allgemeine Theorie der Functionen einer veränderlichen complexen Grösse,” is a basic paper in complex function theory. Weierstrass did not publish his results at the time he first achieved them. His research became known only in the late 1890s when he published his collected *Werke*. Also in analysis, the theory of elliptic functions was developed by Niels Henrik Abel (Norway, 1802–1829) and Carl Gustav Jacob Jacobi (Germany, 1804–1851). The paper that contains Abel's famous theorem was first submitted to the Academy of Sciences in Paris in 1826 for publication in its journal. The manuscript was either disregarded or mislaid, however, and it was not published until after Abel's death, in 1841. A key work in elliptic functions is Jacobi's book *Fundamenta Nova Theoriae Functionum Ellipticarum* (1829).

Developments in geometry affected not only that field, but all the branches of mathematics. Early in the century, three men in different countries all published consistent non-Euclidean systems of geometry, each independently of the other two. In Russia, Nicolai Lobachevsky (1793–1856) published a series of journal articles between 1829

and 1837. In 1840 he published a book in German, *Geometrische Untersuchungen zur Theorie*, in which he lamented the slight interest shown in his writings. His *Pangéométrie*, published in 1855, was a completely new exposition of his geometry. In Hungary, Janos Bolyai (1802–1860) wrote a paper entitled “The Science of Absolute Spaces,” which was published in 1832. And in Germany, Bernhard Riemann, in 1886, published “Über die Hypothesen, welche der Geometrie zu Grundeliegen” (On the Hypotheses Which Lie at the Foundation of Geometry). This paper was based on a lecture he had delivered in 1854 to the faculty at Göttingen. These men showed that the axioms of Euclid were not self-evident truths, as had been assumed for centuries, and that consistent geometries built on other axioms were possible. This idea produced fundamental changes in notions of physical and mathematical space, and the axiomatic method that pervades all modern mathematics is one of the consequences of this discovery.^[2]

The formalistic treatment of algebra and the abstract axiomatic approach to geometry triggered an interest in logic and foundations of mathematics. This interest was redoubled when George Cantor (1845–1918) first published his controversial theory of sets. Cantor’s theory is spread over numerous papers that appeared in *Mathematische Annalen* and the *Journal für Mathematik* from 1874 to 1897. The first significant mathematical studies of logic were *The Mathematical Analysis of Logic* (1847) and *The Laws of Thought* (1854), both by George Boole (1815–1864). In 1884, Gottlob Frege (1848–1925) published *Die Grundlagen der Arithmetik*, which stimulated efforts to unify logic and mathematics.^[1]

As mathematics expanded and changed during the nineteenth century, so too did the agencies for the propagation of results. First, the universities participated in research, the writing of textbooks, and the systematic training of mathematicians. The dominance of the royally supported academies began to decline at this time and research became an important function of the universities.^[2]

Second, there was a vast increase in the number of journals. The first purely mathematical journal, *Annales de Mathématiques Pures et Appliquées*, was started in France in 1810; it ceased publication in 1831. *Crelle’s Journal*, the oldest mathematical journal still in existence, began in 1826. Among the numerous other titles are the *Mathematische Annalen* (Germany, 1868–), the *Acta Mathematica* (Sweden, 1882–), and the *American Journal of Mathematics* (1878–), the first mathematical journal in the United States.

Finally, another type of agency that has promoted mathematical activity since the nineteenth century is the national professional society. With the exception of the Wiskundig Genootschap, founded in Amsterdam in 1778, most national societies did not appear until the second half of the nineteenth century. The oldest of the major national societies is the Moskovskoe Matematicheskoe

Obshchestvo (Moscow Mathematical Society), organized in 1864. Some others are the London Mathematical Society (1865), the Societe Mathématique de France (1872), the American Mathematical Society (1894; founded in 1888 as the New York Mathematical Society), and the Deutsche Mathematiker-Vereinigung (1890). These societies hold regular meetings at which papers are presented and each sponsors one or more journals.

Occasional international meetings of mathematicians took place during the nineteenth century, but the first of the present series of international congresses of mathematicians was held in 1897. The congress has met regularly every four years since 1900, except for interruptions caused by the two World Wars. The *Proceedings* of each congress have been published, usually by the mathematical society of the sponsoring country.^[4]

In 1900, at the International Congress of Mathematicians assembled in Paris, David Hilbert (1862–1943) lectured on mathematics in the new century. Hilbert, who had just published his now-famous *Grundlagen der Geometrie*, a complete revision of Euclid’s *Elements* using modern axiomatic methods, outlined 23 unsolved problems, a challenge for the new century. Hilbert’s insight was so accurate that every one of these problems has led to important new results, but even he could not foresee how mathematics would expand in the 1900s.

The phenomenal growth rate that began in the 1800s continued, with mathematical knowledge doubling every 15 or 20 years. Quantity, however, is not the chief feature of twentieth century mathematics. One of the outstanding characteristics of mathematics of the present century is a fundamental trend toward unity; for an abstract axiomatic treatment of mathematics as a whole.^[5] As a result of Boole’s work and the recognition of formal axiomatics that followed the discovery of non-Euclidean geometries, interest in the logical foundations of mathematics began to spread rapidly. The most notable successor to Boole’s initial efforts in mathematical logic is the *Principia Mathematica*, a monumental two-volume work that appeared during the years 1910–1913. In this work the philosopher-mathematicians Bertrand Russell (1872–1970) and Alfred North Whitehead (1861–1947) attempted to express all of mathematics in a universal logical symbolism. This goal of finding a single consistent set of axioms upon which all mathematics could be based was proved unattainable in 1931 when Kurt Gödel (1906–) published “Über formal unentscheidbare Sätze der *Principia Mathematica* und verwandter Systeme I” (On Formally Undecidable Propositions of *Principia Mathematica* and Related Systems; English translation 1965). Another important book of Gödel’s is *The Consistency of the Axiom of Choice and of the Generalized Continuum Hypothesis with the Axioms of Set Theory* (1940; rev. ed. 1951). Gödel demonstrated that in any axiom system broad enough to contain all the formulas of a formalized elementary number theory, there exist

theorems (formulas) that can neither be proved nor disproved within the system.^[6]

Having accepted the fact that mathematics is not provably consistent from within, mathematicians continued to explore their own branches of the subject. Algebra has become far more general than it has ever been before, and similar tendencies toward abstraction in geometry have led to advances in the field of algebraic geometry and the hybrid field of differential geometry (a synthesis of geometry and parts of analysis). Analysis itself has become more generalized, linked with both algebra and topology. The methods of algebraic topology, which began to be a major field of investigation at the end of the nineteenth century, have become the basis for a newer field, homological algebra.^[7]

The desire to consolidate and simplify previous results can be seen throughout mathematical history; Euclid's *Elements* was an example of this tendency. In the twentieth century, another attempt was begun in the 1930s to integrate all contemporary mathematics within a single framework by a group of French mathematicians writing under the name of "Bourbaki." The work of this group will be discussed in the next section of this article.

During and after World War II, mathematical thinking penetrated the sciences and technology at an ever-increasing rate. In the decades since the war the methodological and conceptual tools of mathematics have been utilized by the social sciences as well.

A measure of the growth and volume of the modern world's utilization of mathematics is given by the estimates that show that of all the mathematicians who ever lived, over 80% are alive today. The U.S. Office of Education, which publishes statistics on the number of degrees granted each year, reports 250 doctorates in mathematics in 1955, 660 in 1965, and predicts 1840 in 1975.

More original mathematics has been produced since the end of World War II than in all previous history. Over 1200 journals publish mathematical articles, of which more than 12,000 were reviewed in the first six months of 1975 by *Mathematical Reviews*.^[8]

It is this literature—the literature since the end of the War—that is the subject of the following section.

THE CURRENT MATHEMATICS LITERATURE

Introduction

As a working hypothesis for its studies on mathematical information exchange, the American Mathematical Society's Committee to Monitor Problems in Communication considered the current mathematics literature to be publications that are reviewed in *Mathematical Reviews*.^[9] This seems to be an acceptable definition for our purposes, also, since *Mathematical Reviews* is the principal abstracting journal of mathematics and covers the world literature in the field. The current literature may

be further defined as that which forms the content of graduate education and represents present-day research interests. Mathematics that is studied at the elementary, secondary, and collegiate levels is a consolidation of results and ideas from the earlier periods of mathematical history and, therefore, does not satisfy the definition of current mathematics. The literature of mathematics below the graduate level is found in the form of textbooks and can be easily located in general bibliographies, indexes, and publishers' catalogs.

Another class of materials that will be omitted from our discussion is mathematical literature for the layman: popularizations, mathematical games and recreations, and so forth. Again, the standard bibliographic tools can be used for locating information about this type of literature.

In the discussion that follows, the mathematics literature is divided into two categories: the primary literature and the secondary literature. After a general description of the types of publications in each category, specific titles are cited as illustrations of the various types.

The Primary Mathematics Literature

The current mathematics literature is chiefly serial in nature. The principal medium for the dissemination of mathematical information is the journal, followed by the book series, including series of monographs, proceedings of symposia, and translation series. The least common form of publication is the nonserial book. In this group are found dictionaries, handbooks, mathematical tables, directories, histories, collected papers of individual mathematicians, and Festschriften. Because of the way the nonserial literature is used, it will be dealt with in connection with the secondary literature.

The broad headings used to classify entries in *Mathematical Reviews* gives an indication of the subject coverage of the literature. The current literature reflects a wide variety of research activity, ranging from traditional topics, such as geometry, to more recent topics, such as homological algebra. The increasing penetration of mathematics into other disciplines is evidenced by literature dealing with the biological and behavioral sciences, in addition to the traditional applications in the physical sciences.

While a reading knowledge of French, German, Italian, and Russian is useful to the mathematician, English has recently become the dominant language in world mathematical circles. For example, in the German journal *Mathematische Annalen*, the percentage of papers in English rose from approximately 5% in the mid-1930s to nearly 20% in the mid-1950s, and to 55% in the mid-1960s.^[7] Most countries with an academic tradition produce at least one mathematical periodical that is internationally recognized. English language abstracts of many articles from these periodicals appear in *Mathematical Reviews*. (A small number of *Mathematical Reviews* abstracts are still written in French, German, and Italian,

however.) The American Mathematical Society also has an active translation program, notably in the area of Russian mathematics, about which more is said later.

Mathematics literature is issued by three general categories of publishers: societies, universities and academies, and commercial houses. All three groups issue both serial and nonserial publications, covering both basic research and applied mathematics. It is not the case in mathematics, as in many subjects, that research is published by institutions and practical applications of the research are reported by the commercial press. There are instances where mathematical societies place their publications in the hands of commercial houses, but this is for the purpose of administrative convenience; Bell of London, for example, is the publisher for the Mathematical Association. Again, unlike the case in other sciences, there are few publications issued by the U.S. government that are of value to mathematicians. The only such publication abstracted in *Mathematical Reviews* is *The Journal of Research of the National Bureau of Standards. Section B: The Mathematical Sciences*.^[10] The National Science Foundation does not publish mathematics under its own name, but gives financial support to other mathematical publications, especially for translations of foreign-language works. An interesting example of such cooperative publishing is a three-volume survey of mathematics that was translated from the Russian: *Mathematics: Its Content, Methods, and Meaning*, edited by A.D. Aleksandrov, A.N. Kolmogorov, M.A. Lavrent'ev, and translated by S. H. Gould and T. Bartha (Russian edition 1956; American edition 1963). A National Science Foundation grant enabled the American Mathematical Society to translate and publish this work, which subsequently received wider circulation by being reissued by the M.I.T. Press.

Journals

The history of scientific journals, as noted earlier, began with the formation of scientific societies and academies in the seventeenth century. These first journals, such as the *Philosophical Transactions of the Royal Society* (London, 1665), contained both mathematical and scientific articles. During the eighteenth century, when journals had become the accepted medium for publication of research, they increased in number. By the nineteenth century they had become more specialized. The *Annales de Mathématiques Pures et Appliquées* (France, 1810–1831) was the first journal devoted solely to mathematics. The *Journal für die reine und angewandte Mathematik*, founded in Germany in 1826, and usually referred to as *Crelle's Journal* (after its founder), is the oldest mathematics journal still in existence.

The number of mathematical journals vastly increased with the establishment of national mathematical societies in the second half of the nineteenth century. Today most countries have national societies that publish at least one

journal. The oldest and largest U.S. society, the American Mathematical Society, publishes six journals.

In addition to national societies, there are a number of societies of a specialized nature that issue journals. Two examples of this type of society are The Mathematical Association of America and the Society for Industrial and Applied Mathematics.

The Mathematical Association of America is concerned primarily with collegiate-level mathematics and teaching, and publishes three journals: *The American Mathematical Monthly*, a journal containing original and expository articles at the undergraduate and beginning graduate level; *Mathematics Magazine*, which is similar in content to the *Monthly*, but focuses at a somewhat lower level; and *The Two-Year College Mathematics Journal*, established in 1970 by the commercial firm of Prindle, Weber, and Schmidt, but published since the fall of 1974 by the association. This journal features articles, book reviews, and problems of special interest to students and teachers in two-year colleges.

The Society for Industrial and Applied Mathematics (SIAM) publishes eight journals in the area of applied mathematics: *SIAM Journal on Applied Mathematics* (formerly the *SIAM Journal*); *SIAM Journal on Control*; *SIAM Journal on Theory of Probability and Its Applications*, which is a translation of the Russian journal *Teoriya Veroyatnostei i Ee Primeneniya*.

Universities also began to issue journals in the nineteenth century. The first mathematical journal in the United States was the *American Journal of Mathematics*, founded in 1878 by J.J. Sylvester when he was a professor at Johns Hopkins University. Currently, many universities with strong mathematics programs, in the United States and worldwide, publish journals; some are general in nature and some are specialized. Two examples from the United States are the *Duke Mathematical Journal* (general) and the *Notre Dame Journal of Formal Logic* (specialized).

Until recently, commercial houses have played a more important role in journal publishing in Europe than in the United States. For example, Springer-Verlag of Germany publishes *Mathematische Annalen* and *Mathematische Zeitschrift*, while in England Pergamon Press publishes *Topology, an International Journal of Mathematics*. In 1960, Academic Press of New York inaugurated an impressive program of publishing journals devoted to special areas of mathematics. Currently it issues the following titles: *Journal of Mathematical Analysis and Applications*; *Journal of Algebra*; *Journal of Differential Equations*; *Journal of Combinatorial Theory*; *Journal of Functional Analysis* (articles in French and English); *Journal of Approximation Theory* (German and English); and, *Journal of Multivariate Analysis* (German, French, and English).

As the foregoing remarks indicate, the current journal literature covers a broad range of topics, is produced by

several different types of publishers, and is issued in all of the modern languages, although English has become the dominant language of mathematical research. Many important foreign language journals are now being translated into English on a continuing basis. (The latest index volume of *Mathematical Reviews* lists the journals in translation that are abstracted in that publication.)

In quantitative terms, the journal literature has experienced the same rapid growth that typifies all scientific and technical literature in general. The latest index issue of *Mathematical Reviews* lists approximately 1200 journals that contain mathematical contributions. Since space does not permit describing them all, the journals published by the American Mathematical Society have been selected for discussion. The publications of the society have been chosen as examples because they illustrate the variety of journals that are available. The society not only issues six journals under its own name, but it publishes translations of foreign journals, it has cooperative agreements with other mathematical societies, and it subsidizes several journals published by universities and other organizations. Furthermore, most of the general comments about the society's journals are applicable to the journals of other national societies.

Of the six journals published under the society's name, two are devoted solely to the results of original research. They are: *Transactions of the American Mathematical Society* (1900–) and *Proceedings of the American Mathematical Society* (1950–). Both of these journals, which are issued monthly, cover all areas of pure and applied mathematics. Ordinarily, longer papers are published in the *Transactions* and shorter ones in the *Proceedings*. A strict editor-referee system, which ensures the highest level of excellence of the papers, makes these among the more prestigious journals in which to publish.

The *Bulletin of the American Mathematical Society* (1891–) is the official journal of the society. A bimonthly publication, it contains reports of the meetings, financial reports, and miscellaneous other material of interest to professional mathematicians. It also contains the full texts of many invited addresses at meetings, long survey articles by invited authors, reviews of advanced mathematics books, and a department of research announcements.

Notices of the American Mathematical Society (1954–) is published eight times a year, primarily to transmit the programs of meetings of the society. It contains author abstracts of all contributed papers for meetings, announcements of research in progress, personal notes, and other news items.

Two journals of the society are devoted to research in special areas. They are: *Mathematics of Computation* (formerly *Mathematical Tables and Other Aids to Computation*, 1943–), which is a quarterly devoted to advances in numerical analysis, the application of computational methods, mathematical tables, high-speed calculators,

and other aids to computation; and *Journal of Differential Geometry*, a publication that began in 1970.

Three journals of Russian translations are currently published by the society. They are: *Soviet Mathematics-Doklady* (bimonthly), which is a translation of the entire pure mathematics section of the *Doklady Akademii Nauk SSSR*, consisting of short reports of current research in the former Soviet Union. It provides a comprehensive, up-to-date survey of what is going on in Soviet mathematics. *Mathematics of the USSR-Sbornik* (monthly) is a translation of *Matematicheskii Sbornik*, which is published by the Moscow Mathematical Society and the Academy of Sciences of the USSR. It deals with current research in all fields of mathematics. The third journal is *Mathematics of the USSR-Izvestija* (bimonthly), which is a translation of *Izvestija, Matematicheskaja Serija*, published by the Academy of Sciences of the USSR and dealing with research in pure areas.

The society also published *Chinese Mathematics-Acta*, a translation into English of *Acta Mathematica Sinica*, which was published from 1960 until 1966 by the Academia Sinica, Peking, People's Republic of China. Until the publication is resumed in Peking, the latest available volume is Vol. 9 (1967).

The American Mathematical Society has entered into cooperative agreements with other mathematical societies, both in the United States and abroad. In the United States, one of the forms this cooperation takes is joining in the support and publication of a number of mathematical journals. It shares with the Johns Hopkins University the publication of the *American Journal of Mathematics*, and it assumes responsibility for the technical editing of the *Quarterly of Applied Mathematics* of Brown University. The society also contributes to the financial support of a number of other mathematical journals. These include, at present, the *Canadian Journal of Mathematics* and the *Rocky Mountain Mathematical Journal*. It also provides editorial services for the *Journal of Symbolic Logic*, a publication of the Association for Symbolic Logic.

Book Series

Mathematical Reviews abstracts books as well as journals, so the headings referred to previously give some indication of the subject coverage of this form of literature. However, books generally do not deal with the latest developments on the frontiers of research. The nature of book publishing is such that older, more established topics are dealt with, usually in an expository manner.

As is the case with journals, books are published by societies, universities and academies, and commercial houses. This is true both in the United States and abroad.

Once again, the American Mathematical Society plays an important publishing role. Its several book series are typical of the kinds of material found in this category and provide good examples for discussion. The society

publishes 13 book series, including several series of monographs, proceedings of symposia, and translation series.

The society's three monograph series are *Memoirs of the American Mathematical Society*, *Colloquium Publications*, and *Mathematical Surveys*. *Memoirs* (1950–) is the longest of the monograph series. It contains research tracts of the same general character as the papers published in the *Transactions*. *Colloquium Publications*, a monograph series that began in 1905, is the oldest of these series and contains the syntheses of recent and older mathematical work prepared by outstanding research mathematicians. *Mathematical Surveys* covers fields of current interest, each volume giving a brief survey of a subject and an introduction to its recent developments and unsolved problems.

The four series of proceedings are: *Proceedings of Symposia in Pure Mathematics*, which contains lectures from symposia and summer institutes sponsored by the society; *Lectures in Applied Mathematics*, which contains a series of lectures given at the summer seminars sponsored by the society; *SIAM-AMS Proceedings*, which contains lectures from symposia and summer institutes in applied mathematics, sponsored jointly with the Society for Industrial and Applied Mathematics; and *Lectures on Mathematics in the Life Sciences*, a recent series dealing with the mathematical aspects of biology.

Society translations include one monograph series and five translation series. They are: *Translations of Mathematical Monographs*, which is a series translated chiefly from the Russian; *Selected Translations in Mathematical Statistics and Probability*, published by the society for the Institute of Mathematical Statistics; *Translations Series I and II*, translated from the Russian and other Eastern European and Oriental languages; *Proceedings of the Steklov Institute of Mathematics in the Academy of Sciences of the USSR*; and *Transactions of the Moscow Mathematical Society*. These last two series are cover-to-cover translations of two Russian series.

The monographs and other serials of the American Mathematical Society may be characterized as advanced research-level publications. To meet the need for expository presentations at the collegiate and graduate level, The Mathematical Association of America publishes two important series. The *Carus Mathematical Monographs* is a series of books in pure and applied mathematics, each written by an authority in the field. The scope of this series also includes historical and biographical monographs. The *MAA Studies in Mathematics* is a series devoted to recent developments in mathematics. Each volume is a collection of reprints of short papers on a given topic by several authors.

Some important foreign series that should be mentioned are:

Cambridge Tracts in Mathematics and Mathematical Physics, a monograph series published by Cambridge

University Press since 1905. The purpose of this series is to provide introductions to modern topics in mathematics. While the books are not intended for specialists, they cannot be considered elementary in the conventional sense.

Ergebnisse der Mathematik und ihrer Grenzgebiete is issued by a commercial publisher, Springer-Verlag of Berlin. Each volume in this monograph series may be described as a state-of-the-art treatment of an individual topic. The treatment of a topic is exhaustive, bringing together and relating results that previously were scattered throughout the literature, primarily the journal literature. Of immeasurable value to the researcher is the extensive bibliography, arranged chronologically, which appears at the end of each volume. German and English are the languages in which these books are published.

Lecture Notes in Mathematics is another Springer publication. This series attempts to report quickly new developments in mathematical research and teaching. The type of material in this series includes preliminary drafts of original papers, lectures on a new field, or presentations of new perspectives on a classical field, and papers from seminars. Each volume is devoted to a single topic and the language may be German, French, or English.

No discussion of the primary mathematics literature would be complete without mention of the works of a nonexistent Frenchman named Bourbaki. Nicolas Bourbaki is the collective pseudonym used by an informal corporation of French mathematicians, numbering from 10 to 20 at any one time. This anonymous society is writing a comprehensive treatise on mathematics, starting with the most general basic principles and to conclude, presumably, with the most specialized application. The treatise, whose general title is *Eléments de Mathématique*, is a survey of all mathematics from a sophisticated point of view. The Bourbaki presentation of each subject is systematic and thorough, often including an historical review of the subject and a set of exercises. The Bourbaki gadgetry includes inserts constituting a set of directions on the proper use of the treatise, foldout sheets that summarize important definitions and assumptions, and a dictionary for each book that serves also as an index to “Bourbachique” terminology. The project, published by Hermann of Paris, got under way in 1939 and over 30 titles of this monumental work have appeared to date. The number of volumes is somewhat larger, since many of the earlier titles have been revised and issued as second and even third editions. The influence of this series is equalled only by the amount of apocryphal stories about Bourbaki, most of them perpetrated by the members of the group.^[11]

The Secondary Mathematics Literature

The secondary mathematics literature is not extensive. Indeed, when compared with the bibliographic tools and

services of other sciences, it is somewhat meager and even primitive. Sophisticated information systems, based on computer technology, have been employed by other disciplines for some time. However, the establishment of machine-readable databases, and the use of the computer to assemble and compose indexes, are very recent developments in mathematics. Within the last five years some new tools and services have resulted from the utilization of new technology, and they are discussed later in this paper.

In examining the secondary literature it might be helpful to view it in terms of the information needs of mathematicians: current awareness (what are the latest developments in a particular field of interest?); day-to-day specifics (is there a solution of this problem? what is the meaning of this foreign term?); and retrospective (what has been written on the history of this topic?).

The need to be informed about recent developments and publications is met by the traditional abstracting and reviewing journals and by the newer current awareness services. Day-to-day needs are met by information contained in monographs, treatises, and reference books, such as dictionaries and mathematical tables. Retrospective needs are satisfied by indexes, collections of reviews, and by bibliographies found in monographs and treatises.^[12]

Current Awareness Needs

By the middle of the nineteenth century the number of mathematical journals and the scattering of mathematical articles over a number of more general periodicals made it difficult for the individual to keep informed, and in 1868 the first mathematical abstracting journal, *Jahrbuch über die Fortschritte der Mathematik*, was founded. Its success was only partial because of a substantial time lag and it ceased publication in 1934. The literature from that time to the present day is covered by the following abstracting journals: *Zentralblatt für Mathematik*, founded in 1931; *Mathematical Reviews*, founded in 1940; and *Referativnyi Zhurnal Matematika*, founded in 1953. A number of specialized abstracting journals have also appeared in recent years: *Statistical Theory and Method Abstracts* and *Computer Abstracts* are two examples.

Mathematical Reviews, published by the American Mathematical Society, is undoubtedly the most valuable English-language publication for locating current mathematical literature. It is international in scope, covering about 1200 journals of every mathematical specialty and every language in which mathematics is written. A special attempt is made to cover the mathematical activities in the USSR and the countries within its sphere of influence. Selected books and other nonserials as well as journals and series are reviewed. Books of a popular nature or below the level of graduate education are not usually included.

Entries from other abstracting and reviewing services are reprinted in *Mathematical Reviews*. They are: *Applied Mechanics Review*, *Computing Reviews*, *Electrical and Electronics Abstracts*, *Mathematics of Computation*, *Operations Research*, *Physics Abstracts*, *Referativnyi Zhurnal Matematika (Mehanika, etc.)*, *Statistical Theory and Methods Abstracts*, and *Zentralblatt für Mathematik*.

In addition to the American Mathematical Society, about 30 other national mathematically oriented societies sponsor *Mathematical Reviews*. The publication was initiated in 1940 with funds granted by the Carnegie Corporation of New York, and over the years it has received support from the National Science Foundation, the Rockefeller Foundation, the American Philosophical Society, and the Alfred P. Sloan Foundation. It is presently facing an uncertain future, due to the recent withdrawal of National Science Foundation and private foundation funding.

The reviews are written by approximately 2000 mathematicians who are experts in the subject areas of the original papers. The reviews, which are critical in nature, describe and evaluate the subject content of the original paper, often reproduce factual data and the steps of proofs, and relate the results to previous works.

Mathematical Reviews is published monthly in two annual volumes, with a separate index issue for each volume. The reviews in each volume are numbered consecutively. Some idea of the exhaustiveness of this work is given by the fact that in the first six months of 1975 (Vol. 49), 12,217 reviews were published.

Reviews in the monthly issues are currently arranged under 61 headings, in accordance with a subject classification scheme developed in 1970. Minor revisions are constantly being made in the scheme, based on literary warrant.

The index volumes include: an author index; a reprinting of the subject classification mentioned above; abbreviations of names of journals abstracted; a list of journals in translation; transliteration of Cyrillic employed by *Mathematical Reviews*, the Library of Congress, and selected abstracting journals; errata and addenda; and, since Vol. 45 (January–June 1973), a subject index. This subject index is a classified one, arranged according to the American Mathematical Society subject classification scheme. Briefly, this scheme consists of the main headings used to arrange the reviews in the monthly issues, which have been further subdivided into more specific subheadings, and to which code numbers have been assigned. Each review in the subject index is listed under the classification code numbers that have been assigned to it. The review is listed under the name of the author of the original paper and reference is to the number of the review.

Periodic cumulative author indexes are also published and are discussed later in this paper.

Zentralblatt für Mathematik und ihre Grenzgebiete is published in Berlin by Springer-Verlag, with editorial

offices at Deutsche Akademie der Wissenschaften and Heidelberger Akademie der Wissenschaften (both in Berlin). Like *Mathematical Reviews* it is international in scope, has signed abstracts of the literature in various languages (chiefly German and English), is arranged in classified order (using the American Mathematical Society scheme at the present time), and has author indexes. It also has separately published cumulative author indexes.

Since late 1973 *Zentralblatt* has been gradually changing over to the use of author abstracts in an effort to satisfy the demand for more rapid and comprehensive information about mathematical research. This procedure, according to the publisher, is intended to lead to a certain degree of differentiation and complementation between the mathematical reviewing/abstracting journals. The journal has advised authors that an abstract should not be a short summary, but should comply in size and form with a normal review (although criticism is not expected) and may be written in English, French, or German. If authors' abstracts can be published within 10 weeks of receipt, as *Zentralblatt* hopes to do, this will be a great improvement over the time lag of many months that now exists.

Referativnyi Zhurnal has been issued since 1953 by the Akademiya Nauk SSSR, Institut Nauchnoi Informatsii, Moscow. It is a major abstracting journal for the world's literature in most branches of science and technology.

Referativnyi consists of several series, designated *svodnyi tom* (joint volume), each devoted to an individual branch of science or technology. The number and titles of the series have varied over the years. A series, or joint volume, is made up of chapters that are issued as separate periodicals with their own titles, and designated *vypusk RZh* (section of the *Referativnyi Zhurnal*). The mathematical series is titled *Referativnyi Zhurnal Matematika* and consists of three chapters: General. Mathematical logic. Theory of numbers. Algebra. Topology. Geometry.-Mathematical analysis.-Numerical analysis. Probability theory and mathematical statistics. Cybernetics.

Bibliographic information in *Referativnyi* is listed in the original languages following the Russian entry. There is a monthly author index.

As the volume of literature has steadily increased, the abstracting and reviewing journals have found it increasingly difficult to remain current. For example, the number of abstracts in *Mathematical Reviews* has been doubling every eight or 10 years, and presently there is a time lag of up to two years before an article or book is reviewed. The active researcher must depend largely on personal communications among members of invisible colleges, according to procedures that differ from those of ancient times only in the media of communication and travel.^[12]

As noted above, the publisher of *Zentralblatt* is hoping to improve the currency of that journal by the device of authors' abstracts. The American Mathematical Society,

as a by-product of converting the database of *Mathematical Reviews* to machine-readable form, was recently able to offer two new current awareness services.

The first service, the Mathematical Title Service, provides lists of titles in all areas of mathematics, based on detailed interest profiles of the subscribers. This service originally started in 1968 as an experiment in automatic dissemination of information, was then called the Mathematical Offprint Service, which supplied offprints of articles. Articles that satisfied the subscriber's interest profile were mailed to him on a continuing basis, along with title listings of articles in which he indicated a peripheral interest. However, this service was discontinued because it could not be made self-supporting, and it was replaced by the Mathematical Title Service.^[13]

The second service was a biweekly alerting journal, *Contents of Contemporary Mathematical Journals*, started in 1969, which reprinted the tables of contents of about 240 mathematical journals. In 1972 the title was changed to *Contents of Contemporary Mathematical Journals and New Publications*, when the scope of the journal was enlarged to include books and other separately published materials. (This type of publication had formerly been announced in the *Notices*.) In early 1974 the format of *Contents* was completely revised. It no longer reproduces title pages of journals, but is a listing of the material (articles, books, collections, etc.) that has been received in the editorial offices of *Mathematical Reviews* during a specific period of time and that is to be eventually reviewed. The material is arranged in classified order according to the major sections of the American Mathematical Society subject classification scheme. In each issue there is also an author index and a list of the journals represented in the issue. The increased coverage is an advantage of this new publication, but the information is not as prompt as formerly, since the materials must now be processed before *Contents* is printed. It remains to be seen whether this factor, plus the harder-to-use format will reduce the usefulness of this publication.

Day-to-Day Needs

As noted earlier, the least common form of literature is the nonserial publication. This category includes dictionaries, handbooks, mathematical tables, and directories, which are used to answer specific questions. It also includes indexes, bibliographies, and expository materials (histories, essays, collected papers of mathematicians, etc.), which meet retrospective needs and which are discussed later in this section.

There are relatively few reference books that answer day-to-day specifics. The mathematician is usually required to locate such information in treatises or other nonserial publications. The types of reference books that

are available, together with some representative titles, can be dealt with briefly.

The dictionary is one of the more useful types of reference tool available to mathematicians. Mathematical dictionaries are often encyclopedic in nature, presenting condensations of mathematical concepts, not merely word definitions. *Mathematics Dictionary*, by Glenn and Robert James, is an example of this type. Another kind of dictionary is the bilingual or multilingual one, of which the *Russian-English Dictionary of the Mathematical Sciences*, by Lohwater and Gould, is an example. Dictionaries of special terms represent still another type; e.g., *Dictionary of Statistical Terms*, by Kendall and Buckland.

The *Mathematical Handbook for Scientists and Engineers*, by Korn and Korn, *Tables of Series, Products and Integrals*, by Ryshik and Gradstein, and the *Combined Membership List of the American Mathematical Society, The Mathematical Association of America, and the Society for Industrial and Applied Mathematics* are examples of handbooks, mathematical tables, and directories, respectively.

Retrospective Needs

The situation with respect to retrospective needs is similar to that for day-to-day needs. Again, the difficulty lies partly in the lack of adequate reference sources and search systems. Mathematics is substantially behind other sciences not only in the preparation of quick reference materials but also in the compilation of indexes, bibliographies, and expository materials, such as encyclopedias and historical studies. And again, as is the case with respect to day-to-day needs, treatises and monographs are used as supplements to, or substitutes for, reference books. As noted earlier, treatises and monographs usually contain extensive bibliographies, and mathematicians tend to use these sources, rather than more general, separately-published bibliographies.

The American Mathematical Society has again taken the lead in attempting to correct this situation. From time to time it publishes comprehensive indexes and collections of reviews in specialized areas.

The cumulative indexes published by the society are: the *20 Year Author Index of Mathematical Reviews, 1940–1959*, (Vols. 1–20); *Author Index of Mathematical Reviews, 1960–1964*, (Vols. 21–28); and *Author Index of Mathematical Reviews, 1965–1972*, (Vols. 29–44). It is interesting to note that the first two cumulative indexes cover 25 years in four volumes and contain 156,000 reviews. The latest index covers eight years in four volumes and contains 127,000 reviews.

The Index to Translations, (1966) is a cumulative author and subject index to material published in three of the society's translation series: *Translations Series I*; *Translations Series II*; and *Selected Translations in Mathematical Statistics and Probability*. In 1974 a second

volume of the *Index* was published, covering the years 1966 through 1973.

The volumes of reviews published by the society are: *Reviews of Papers in Algebraic and Differential Topology, Topological Groups, and Homological Algebra*, containing reviews that appeared in *Mathematical Reviews* from 1940 through 1967; *Reviews of Papers on Infinite Groups*; *Reviews of Papers on Finite Groups*; and *Reviews of Papers in Number Theory*. These last three volumes contain reviews that appeared in *Mathematical Reviews* from 1940 through 1973. The reviews in all of the volumes are arranged in classified order and each volume has an author index. Of special interest are the forward citations given at the end of many reviews. These citations take note of any references made to the article at a later date by a review or reviews in the collection. The advantage of a review volume of this type is that it brings together in one location material that previously had to be searched in several volumes. One must bear in mind, however, that only reviews that appear in *Mathematical Reviews* are included.

CONCLUSION

Mathematics has conformed to the general pattern of explosive exponential growth that typifies all of the sciences. The unprecedented demands made upon mathematics by contemporary society have resulted in an increase in the number of mathematicians and a corresponding increase in the mathematics literature. From 1868 (the year the first abstracting journal was founded) until 1966, the literature grew from approximately 40,000 to about 430,000 titles.^[14] If the estimated 2.5% annual rate of increase continues, the total should exceed 620,000 by the end of the 1970s.

Medical Library Association (MLA)

Carla J. Funk

Medical Library Association, Chicago, Illinois, U.S.A.

Abstract

The Medical Library Association (MLA) aspires to be the association of the most visible, valued, and trusted health information experts working to enhance the quality of health care, education and research throughout the world. MLA fulfills its mission and goals through its continuing education, credentialing, professional recognition, research, publications, and international programs. The association also offers career services and advocates on behalf of its members through the association's public relations program and governmental relations programs. This entry explains how MLA serves its members, the profession, and society through its programs and services.

INTRODUCTION

The Medical Library Association (MLA), a 501(c)3 not-for-profit educational association, is a leading advocate for health sciences information professionals worldwide. Through its programs and services, MLA provides life-long educational opportunities, supports a knowledgebase of health information research, and works with a global network of partners. The association also promotes the importance of quality information for improved health to the health care community and the public. The association's organizational structure includes a board of directors, committees, a variety of task forces, sections organized by special subject interests and areas of responsibilities, ad hoc special interest groups (SIGs), representatives to allied organizations such as the National Information Standards Organization, and affiliated chapters representing the United States and parts of Canada. MLA aspires to be the association of the most visible, valued, and trusted health information experts working to enhance the quality of health care, education, and research throughout the world.^[1] This entry explains how MLA serves its members, the profession, and society through its programs and services.

PROFESSIONAL AND MEMBERSHIP RECRUITMENT

Founded on May 2, 1898, by four librarians and four physicians, MLA is the second oldest special library association in the United States. The Association of Medical Librarians (as it was known until 1907) was founded "to encourage the improvement and increase of public medical libraries." More than a century later, MLA has grown to a professional organization of about 4000 members including 3300 health sciences librarians and 670 health

sciences libraries and institutions in the health information profession. MLA also has international members from 56 countries in addition to the United States and Canada.

Working through its organizational structure (Fig. 1), the association continues to assist librarians with the exchange of health sciences books and periodicals (the MLA Exchange is one of the founders' earliest and most important projects) and to develop a variety of programs and services to serve the needs of health information specialists.

Demographically, MLA is comprised primarily of white females, in their 50s with master of library science (MLS) degrees, who are employed in hospital settings. This description is based upon data from the Hay Group/MLA 2008 Salary Survey.^[2] Thirty-nine percent of MLA's members are employed in hospital libraries, 34% in academic medical centers, and 27% in other settings such as pharmaceutical companies. Eighty-nine percent of the membership is white, 3% Asian, 2% African-American, and 3% Hispanic or other backgrounds. In 2008, the median annual salary for a health sciences librarian was \$60,000 and the average annual salary, \$65,796. Between 2002 and 2008, actual wage rates of health sciences librarians were slightly higher than projected by CPI data.

Membership recruitment and retention is becoming more challenging for a variety of reasons for both the national association and affiliated chapters. The majority of health sciences librarians who entered the profession in the 1970s after the passage of the Medical Library Assistance Act are now retiring. Downsizing and consolidation in the health care industry have resulted in fewer health sciences libraries and fewer health sciences librarians. Although a record number of new members have joined MLA since 1997, these members do not offset those who are leaving the association due to retirement or change in profession. The Membership Committee continues to work to recruit members into the association.

Medical Library Association Structure Chart

**Fig. 1** MLA structure chart.

To meet the challenge of recruiting people into the profession, MLA established the Professional Recruitment and Retention Committee in 2006. The committee has developed initiatives to recruit an increasingly diverse group of people into the profession of health sciences librarianship. Through a series of awards from the National Library of Medicine (NLM) (<http://www.nlm.nih.gov>) and the South Central Region of National Network of Libraries of Medicine (<http://nnlm.gov/scr/>), MLA began a program to recruit people from diverse cultural backgrounds into health sciences librarianship. Through the awards, MLA was able to increase the number and stipend amount of GSLIS scholarships and develop career materials, in both English and Spanish, to inform students about opportunities in the profession. MLA is also actively involved with NLM, in the American Library Association's Spectrum Initiative. MLA launched its mentoring Web site (<http://www.mlanet.org/mentor/>) in 2003, to link people in the profession with interested students and other professionals and developed a "recruitment into the profession" DVD (http://www.mlanet.org/career/career_vid.html).

PROGRAMS AND SERVICES

MLA fulfills its mission and goals through its continuing education, credentialing, professional recognition, research, publications, and international programs. The association also offers career services and advocates on behalf of its members through the association's public relations program and governmental relations programs. In 1994, MLA adopted the Code of Ethics for Health

Sciences Librarianship (<http://www.mlanet.org/about/ethics.html>). The code describes the goals and principles for ethical conduct for its members in relation to society, their clients, their institutions, the profession, and themselves. MLA promulgates practice standards for membership segments such as hospital librarians and chiropractic librarians and promotes research in the provision of information for quality health care.

LIFELONG LEARNING

Medical practice, research, and technology continue to change at a breathtaking pace. Supporting and promoting lifelong learning opportunities for health sciences librarians to meet these future challenges has been a major priority of MLA for almost 50 years. Lifelong learning includes both MLA's continuing education and credentialing programs. These have recently been combined with MLA's research programs to form the Center of Research and Education (CORE) Program. The history of the programs since the 1970s is described in detail in the first edition of the *Encyclopedia of Library and Information Science (ELIS)*^[3] and in a supplement published in 1977.^[4]

Continuing Education

Major changes occurred in the continuing education (CE) program during the 1990s due to the costs involved in administering the program, the need to more quickly incorporate new trends and topics into the course offerings, and the demand to make educational opportunities more

accessible using new technologies. Today, CE courses are no longer designated as core or basic courses and new perspective courses, but are organized by areas of knowledge and skills needed by health sciences librarians as described in the Educational Policy Statement of the MLA: Competencies for Lifelong Learning and Professional Success (<http://www.mlanet.org/education/policy/>).^[5]

Courses are offered at the association's annual meeting and by chapters at their annual meetings. Also, MLA's annual meeting schedule frequently includes symposia on important topics, such as scholarly publishing and leadership development. The course approval process (<http://www.mlanet.org/education/cech/cedevelop.html>) is a rigorous one, and course evaluations are carefully considered by the Continuing Education Committee (CEC). Contact hours are awarded to course participants based upon the number of hours students are in class.

The MLA CEC and headquarters staff worked together to establish MLA's Educational Clearinghouse (<http://cech.mlanet.org>), an online listing of continuing-education opportunities, from a variety of sources that support the core competencies deemed necessary and appropriate for health sciences librarians in their professional development. The Educational Clearinghouse has proven to be an effective resource in furthering health sciences librarians' professional development. Currently information about over 200 courses is available through the clearinghouse. MLA is also working with the National Training Center and Clearinghouse (NTCC) (<http://nnlm.gov/ntcc>), part of the National Network of Libraries of Medicine (NN/LM), to add the NTCC's courses and tutorials to MLA's Educational Clearinghouse.

The kinds of courses offered, both in subject matter and in format, have also changed. The increasing number of courses about Internet applications reflects the tremendous change in the practice of health sciences librarianship over the past 10 years. Courses such as searching the Web for quality health information, developing Web-based CE courses, negotiating licenses for electronic journals and databases, expert searching, and consumer health have been offered. MLA also continues to address the challenge of offering quality and affordable professional development opportunities to people both regionally and at their desktops. MLA's first teleconference in 1996, "The Role of the Library in Accreditation," was received by over 100 sites in the United States and Canada and was seen by about 1300 people. MLA now offers Webcasts to both groups and individuals and provides access to a number of Web-based courses and tutorials on a variety of profession-specific topics.

The demand for Web-based courses continues to increase, and this demand will prove challenging for small associations with few staff and fewer financial resources. To meet this demand, MLA also partners with graduate schools of library and information sciences; supports development of specialty specific Web-based courses; provides

access to Web-based courses from other providers; and develops less costly, local opportunities for CE including independent learning opportunities and discussion groups. Success in effectively using new technologies in this area is essential for the continued success of MLA's continuing education program. Since 2008, MLA has provided hosting services for e-learning courses to encourage the development of these important learning formats.

MLA's move into distance education has increased participation in the association's continuing education program over 700% from 1990 (1,245 participants) to 2008 (9,210 participants).^[6,7]

Specialist credentials

In 2000, MLA established a specialist program in consumer health (CHIS), developed for health sciences librarians as well as other librarians working in the area of consumer health. The program consists of basic and advanced courses on various aspects of consumer health (<http://www.mlanet.org/education/chc/>) taught by health sciences librarians. The program was introduced in 2001 at the "The Public Library and Consumer Health" Conference cosponsored by MLA, the Public Library Association, and the National Library of Medicine. By 2008, almost 400 librarians had received the CHIS credential.

Credentialing and the Academy of Health Information Professionals

MLA has the oldest ongoing recognized credentialing program in the library profession. MLA established the Academy of Health Information Professionals (AHIP) (<http://www.mlanet.org/academy/>) in 1989 to encourage individual professional growth and lifelong learning in health sciences librarianship. The academy replaced a test-based certification program that had been in place since 1973. Since health sciences librarians work with physicians, nurses, and allied health workers who require licenses or certifications and recertifications to continue to practice in their chosen professions, health sciences librarians also felt a need to seek additional credentials beyond the MLS as a way to document their continuing education and demonstrate continued competency in their profession. Today, admission to the Academy is based upon educational qualifications, documented knowledge in established knowledge and skills or competencies areas, and professional contributions through teaching, publishing, or holding leadership positions in the association and its units.

Membership in the Academy is open to both MLA members and nonmembers. Over 1000 health information professionals belong to the academy at one of five levels: provisional, member, senior, distinguished, or emeritus member. Data from the 2008 Hay Group/MLA Salary Survey^[2] indicated that academy members were better compensated than nonmembers, but more analysis is

needed to establish a cause and effect relationship. MLA, through its Credentialing Committee and mentorship program, continues to simplify the application process to encourage membership in the Academy as part of an individual's lifelong learning program.

ADVOCACY

MLA plays a strong advocacy role on behalf of its members to demonstrate the value of quality health information to society and the role that health information professionals play in producing and managing that information. This is achieved through the association's professional recognition, governmental relations, and public relations programs.

Professional Recognition

The grants and scholarships program (<http://www.mlanet.org/awards/grants/>) and the awards program (<http://www.mlanet.org/awards/>) remain strong components of MLA's professional recognition program. At the close of 2008, endowment funds for this purpose represented 44% of the association's total assets.

Grants and scholarships

MLA offers a variety of scholarships and grants administered by the Grants and Scholarships Committee. These stipends assist qualified students, including minorities to attend graduate schools of library and information sciences and enable practicing health sciences librarians to take advantage of opportunities for continuing professional development. This program also enables recipients to attend meetings and conferences and do research important to the practice and progress of the profession.

For example, in 2001, MLA established the Lindberg Research Fellowship, honoring Donald A.B. Lindberg, M.D., director of the National Library of Medicine (NLM), in recognition of his significant national and international achievements at NLM, the world's largest medical library. This research fellowship, given annually, strives to provide a more formal structure for supporting research activities that will benefit the health information sciences by strengthening the knowledge base of information research and improve the practice of health sciences librarianship.

Awards

The awards program, administered by MLA's Awards Committee, honors superior individual achievement in specific areas of health sciences librarianship including hospital librarianship, collection development, history or philosophy of the profession, chapter programs, education,

research, governmental relations, and distinguished public service. Named in honor of distinguished health sciences librarians such as Estelle Brodman, Lois Ann Colaanni, Eileen Cunningham, Louise Darling, Janet Doe, and Lucretia McClure (<http://www.mlanet.org/awards/honors/fellows/>) and honorary members and sponsored by MLA corporate partners important to health sciences libraries, awards are given annually. MLA also honors those who have made outstanding and sustained contributions to the advancement of the purposes of MLA through fellowships and honorary memberships.

Governmental Relations

MLA's governmental relations program (<http://www.mlanet.org/government/>) addresses national information issues and policies that affect the health sciences library community. The association testifies before Congress on a regular basis on the importance of the National Library of Medicine to the provision of clinical and scientific information that supports medical education, research, and, ultimately, improved patient care. MLA has published position papers on a number of issues including fair use, copyright, scholarly publishing, open access, patient safety, and distance education. The association also works in coalition with the other major library associations such as the American Association of Law Libraries and the Special Libraries Association on issues of mutual concern in copyright and scholarly publishing. MLA will continue to partner with other organizations to address information access issues as they continue to evolve in this very complex digital environment.

Public Relations

MLA began a major public relations effort in 1996 to help promote the association's Centennial Celebration in 1998. Today, the program focuses on assisting MLA members and other health sciences information professionals to market their expertise and services both to their institutions and to outside publics. MLA provides a number of advocacy resources (<http://www.mlanet.org/resources/index.html>) including posters for librarians to use in their institutions to heighten awareness of the value of the services provided by the medical libraries and librarians. The association has designated October as National Medical Librarians Month (<http://www.mlanet.org/resources/nml-month/index.html>) to help members promote their services to their institutions and users.

Deciphering MedSpeak publications

The public relations program also aims to create awareness of the health sciences library and information profession through several outreach initiatives to consumers. Distribution of consumer health information such as the

Deciphering Medspeak series, in both English and Spanish (<http://www.mlanet.org/resources/medspeak/>) provides general and disease specific health and Web site information to the public in a simple format, creating awareness of the profession and assisting the public.

Health information literacy

MLA's health information literacy initiative began in 2003 with the appointment of a Health Information Literacy Task Force that studied how health sciences librarians could put "information" into health literacy initiatives, resulting in a number of resources (<http://www.mlanet.org/resources/healthlit/>). This work continued through 2008 with a major health information literacy research project funded through a contract with NLM to study health providers' perceptions of health information literacy and develop a curriculum to support these initiatives in the hospital. With the Pew Internet and American Life Project, MLA members also developed a user's guide to finding and evaluating health information on the Web (<http://www.mlanet.org/resources/userguide.html>) and other consumer resources.

MLA will continue to use its public relations program as an advocacy tool for the profession by addressing the needs of specific membership segments such as hospital librarians or academic medical center librarians. Members increasingly recognize the important role public relations can play in the perceived value of the library and librarian to the institution and to the community.

CREATING AND COMMUNICATING OUR KNOWLEDGE

Research

Part of MLA's mission is to promote research in information management and the profession. Several of the association's grants and scholarships provide stipends for those interested in doing research that will contribute to the profession's body of knowledge. In 2007, MLA published a revision of its research policy statement. The Research Imperative (http://www.mlanet.org/research/policy/policy-of_toc.html).^[8] The revised statement encourages new directions for the association's research program. In 2008, MLA, working through its Research Section, adopted a research agenda to guide the association and its members in research efforts. In addition, MLA sponsors research studies in areas that will help the profession. For example, the MLA Benchmarking Network (<http://www.mlanet.org/members/benchmark/>) offers hospital, academic, and specialty health libraries an opportunity to learn more about benchmarking, compare data, establish best practices, and identify and work with a benchmarking partner. Hundreds of health sciences libraries nationwide participate. Other

studies including MLA's Vital Pathways Project for Hospital Librarians (<http://www.mlanet.org/resources/vital/>) deal with the compensation, the value of information services to institutions' bottom lines, and new roles for health sciences information professionals (<http://www.mlanet.org/research/index.html>). MLA also posts presentations and posters presented at the association's annual meetings on MLANET and has developed a member area on the Web site, the CORE Toolbox, where members can exchange ideas, research, and other helpful information. The association will continue to partner with other organizations to provide research data and resources that will assist health sciences librarians and the public.

Publications

The association's publications program, accomplished through the work of the *JMLA* and *MLA News* Editorial Boards and the Books Panel, encourages and publishes research in health sciences librarianship, provides texts for those studying to be health sciences librarians, provides authorship opportunities for health sciences librarians, and provides consumer health materials for the public. The venerable *Journal of the Medical Library Association (JMLA)* (<http://www.mlanet.org/publications/jmla/index.html>) published almost continually under several names since 1902, was one of MLA's first regular publications. The journal has been made freely available electronically since January 2000 over *PubMed Central (PMC)*, a digital archive of life sciences journal literature developed and managed by the National Center for Biotechnology Information (NCBI) and NLM. In 2006/2007, NLM, working with MLA Headquarters, made the full-text archives of the journal from 1902 freely available online through PMC, putting into practice MLA's support of open access. This is an excellent resource for the study of health information sciences and the management of knowledge-based information.

A Handbook of Medical Library Practice^[9] was one of the first texts published by MLA in the association's book publications program and went through four editions over a 40-year period. The handbook was succeeded by *Current Practice in Health Sciences Librarianship*,^[10] a multivolume series completed in 2001. Until about 1990, all association publishing was centralized at MLA headquarters. In 1990, MLA began working with a series of copublishers to produce a number of noteworthy books and other resources, adding to the research base of the profession (<http://www.mlanet.org/order/index.html>). This includes *The Medical Library Association Guide to Managing Health Care Libraries*,^[11] recognized as "the new gold standard in health sciences library textbooks."^[12]

During the 1990s, MLA expanded its publishing program (<http://www.mlanet.org/publications/>) to include DocKits and BibKits. These publications are collections

of documents or bibliographies of resources about specific topics and are published in-house. MLA also publishes materials in compact disc and digital formats to make information more widely available. Other components in the program are house publications (annual report, Directory, MLA-FOCUS) and *MLA News* (<http://www.mlanet.org/publications/mlanews/>). Experimentation with alternate formats will continue for the foreseeable future as the association continues to convert print products into electronic ones and develop new digital products and services.

Professional Networking

Since associations were one of the early ways in which people of common interests came together, it is not surprising that associations have adopted an increasing variety of social networking tools for the benefit of their members. The association's Web site, MLANET (<http://www.mlanet.org>) provides MLA with a global reach and reveals the richness of our resources and the expertise of our members as never before possible. MLANET not only provides organizational information about MLA, the Web site also provides member networking services; acts as a resources gateway; contains career, educational, and recognition information; and provides online access to research, standards, and publications.

For many years, MLA has supported MEDLIB-L (http://www.mlanet.org/discussion/medlib_l_faq.html), a discussion list that has over 2100 member and nonmember participants. The list is used for interlibrary loan, reference, announcements, and other items that help health sciences librarians in their daily work. MLA headquarters

staff also support more than 100 discussion lists, blogs, wikis, and other social networking tools for association units and provides space on MLANET for section and chapter Web sites. Most recently the association has supported blogs, wikis, and RSS feeds for various association units to improve communications and collaboration.

MLA's annual meeting (<http://www.mlanet.org/am/index.html>) (Fig. 2), held annually in May, continues to be the top face-to-face professional networking event for the profession. It is an opportunity to present and discuss papers, posters, applied research, and important issues in health sciences information management. The event gives MLA members and affiliated professionals a chance to share ideas, hear from experts, see the latest products, network, and socialize. MLA has actively begun to push annual meeting content out to members who can't attend through a variety of social media tools.

BUILDING A NETWORK OF GLOBAL PARTNERS

MLA works actively to serve health care providers and the public through a global network of members and partners who share expertise and resources. Some of the programs already mentioned support this goal through collaborations among the association's sections and chapters, other library associations and organizations, and the international library and information community. In the international arena, MLA is a longtime active member of the International Federation of Library Associations and Institutions (IFLA) and supports the International Congress on Medical Librarianship (ICML) held every 4–5 years around the world. MLA's global initiatives are a part of

Fig. 2 MLA's annual meeting is the premier event in the health information sciences profession.

Fig. 3 2007/2008 MLA President Mark E. Funk, AHIP (center, back row), with members of the South African National Health Information Partnership at the 2007 IFLA Conference and Exhibition in Durban, South Africa.

the association's Librarians without Borders® program (<http://www.mlanet.org/resources/global/>) that includes a sister library initiative, a world-wide e-library training program, and the T. Mark Hodges International Service Award program. MLA also has bilateral agreements with the Canadian Health Libraries Association/ABSC, the German Working Group, the European Association of Health Information Libraries, the Association for Health Information and Libraries in Africa (AHILA), and the Korean Medical Library Association (KMLA) and connects with health sciences librarians throughout the world (Fig. 3)—a truly global organization.

In 2006, MLA assumed management of the Association for Library and Information Science Education (ALISE) strengthening our ties with the library education community. Founded in 1915 as the Association of American Library Schools, ALISE provides a forum for library educators to share ideas, to discuss issues, and to seek solutions to common problems. MLA members also formally represent MLA at a number of other allied organizations (<http://www.mlanet.org/about/leaders/allied.html>).

CONCLUSION

MLA continues to work actively to recruit people into the health sciences information profession, to promote and support lifelong learning, to advocate on behalf of the profession, to create and communicate the profession's knowledge, and to build a network of global partners to serve the member, the profession, and society. For example, the association is working on several future challenges for the profession concerning roles of the health sciences librarian, including the Vital Pathways Project for Hospital Librarians and the Health Information

Literacy Research project. The association is also furthering the concept of evidence-based medicine through the support of conferences and publications in this area. Future challenges for MLA as for many other associations are in the areas of membership recruitment, technology, finances, outside competition, and environmental impacts. Keeping up with new technologies to provide programs and services is a tremendous challenge for a small association. However, MLA continues to be a vital organization after more than 100 years of operation. One of the major reasons that the association was founded was to provide for an exchange of materials among its membership. Today, the MLA Exchange is transmitted electronically among 900 subscribers and has become just one of many programs and services that MLA provides for its membership. MLANET, MLA's Web site, is the association's face to the world, enabling a librarian in India to teach MLA's health literacy and health information literacy concepts to medical staff and librarians from Australia and Asia to participate in its Web-based courses. There has never been a more exciting or challenging time to be a librarian or a library association staff member.

Medical Literature: History [ELIS Classic]

William K. Beatty

Northwestern University Medical School, Chicago, Illinois, U.S.A.

Abstract

One of the objectives of the information disciplines is to study the universe of recorded information—that is, to study the documentary products of domains of human activity—and to come to understand such bodies of literature as social and historical phenomena in and of themselves. Beatty discusses the rich history of medical literature from ancient times to the mid-twentieth century. Forms of bibliographic control, such as *Index Medicus*, are also covered.

—ELIS Classic, from 1976

INTRODUCTION

The earliest extant piece of medical literature is a Sumerian clay tablet that contains medical recipes. This tablet, approximately 4 × 7 inches and made of baked red clay, probably dates from about 2100 B.C. It is written in Sumerian cuneiform and contains 15 prescriptions but no supernatural elements. The Code of Hammurabi, from approximately the same time, includes some regulations on medical practice and penalties for failure to produce a cure.

Many of these clay tablets, or rather in most cases fragments of clay tablets, were in the collection of King Assurbanipal of Assyria who lived in the seventh century B.C. The British Museum has over 30,000 of these, several hundred of which are medical. Many drugs, plants, and minerals are referred to in medical prescriptions, and some tablets also contain incantations. One series of these tablets was used for letters from the royal physician, Aradnana, to King Esarhaddon.

The papyri from Egypt, most of which were written around 1500 B.C. (although their contents in some cases include much older material), present interesting examples of the early medical literature. The oldest of these, written about 1900 B.C., was discovered by Sir Flinders Petrie in 1889 at Kahun. The Kahun Papyrus is now at University College in London. A transcript and English translation by F.L.I. Griffith was published in 1898. Three pages in length, this papyrus deals with gynecological material.

A major surgical papyrus, the Edwin Smith, dates from about 1600 B.C. and was obtained at Luxor in 1862 by Edwin Smith, an American. The papyrus itself is at the New York Academy of Medicine; a translation and transliteration of it was published by James H. Breasted in 1930. This roll is a little less than 16 feet long, 1 foot wide, and has writing on both sides. The 17 columns on the front describe 48 cases, most of which involve injuries to the head, chest, or spine. The five columns on the back contain charms unrelated to the material on the front.

The most famous of these medical papyri is the Papyrus Ebers, written about 1550 B.C. This was discovered about 1860 and acquired at Thebes by Georg Ebers in 1873. Most of the material in it comes from a much earlier period, perhaps as far back as 3000 B.C. The Ebers is the only papyrus extant that is complete. The roll was originally 68 feet long, a foot wide, with 108 columns of 20 lines each. It was later cut into pages and bound as a modern book. This is now in the University Library at Leipzig; a translation by Ebbell was published in London in 1937. The text consists primarily of 877 prescriptions, one of which contains 37 ingredients. Frequently occurring items include opium, hellebore, salts of lead and copper, and blood, excreta, and viscera of animals. The last section describes the treatment of tumors.

Also from about 1550 B.C. is the Hearst Medical Papyrus, named for Mrs. Sophie B. Hearst who gave the money for the excavations that produced it. This papyrus is preserved at the University of California. The scroll contains 18 columns and is incomplete. It consists of a formulary (apparently used by a practicing physician) quite similar to parts of the Ebers Papyrus. Both papyri probably came, at least in part, from the same source. The Hearst Papyrus also contains descriptions of three methods for uniting bones. A translation into German and a transliteration by Wreszinski appeared in 1901.

The Berlin Museum has a papyrus of 15 columns dealing with childbirth and infants, which also dates from about 1550 B.C. This was translated into German by Erman in 1912. The British Museum in 1860 purchased the London Medical Papyrus, which was written about 1350 B.C. In 1912, Wreszinski published a German translation of this. Wreszinski also published in 1912 German translations of the Berlin Medical Papyrus and the Brugsch Maior Papyrus. Both of these are preserved in Berlin. They date from about 1300 B.C., and the former contains some 200 prescriptions. The Chester Beatty Papyrus, with eight columns extant, concerns diseases of the anus and

was probably written around 1200 B.C. Jonckheere published a French translation in 1947.

The Babylonian Talmud includes considerable material on anatomy and surgery, although this is mostly embedded in statements about the law. Tumors of the lungs, diseases of the liver, and diphtheria are also mentioned. Amputations, trephining, and other surgical procedures are referred to briefly. The Old Testament contains many regulations dealing with public health and hygiene. The isolation and care of individuals with contagious diseases, and the prohibition of certain foods (with logical overtones of preventing sickness) form the bulk of this material.

EARLY GREECE, INDIA, AND CHINA

Items of medical and surgical treatment appear in Homer, mostly in the *Iliad*, but the Greek medical literature itself did not actually begin until Alcmaeon of Crotona, a younger contemporary of Pythagoras and the most famous Greek physician before Hippocrates. Only a few fragments of Alcmaeon exist. He is credited with the discovery of the optic nerve, knowledge of the trachea, and the belief that the brain was the central organ of intellectual activity. Other pre-Hippocratic authors of importance include Anaxagoras, who wrote of the dissection of animals and recognized the lateral ventricles of the brain, Empedocles, who was the first to formulate the theory of the flux and reflux of the blood from and to the heart, and Diogenes of Apollonia, whose small book on the heart became the outstanding anatomical work in the Hippocratic Corpus and exerted considerable influence.

The Hippocratic Corpus is a large collection of medical writings, some credited to Hippocrates but most of which were probably written by pupils or even later authors. These range from medical textbooks and reports of investigations, through lectures for medical students all the way to works obviously intended for laymen. The works that are generally attributed to Hippocrates include the three books of Epidemics; Regimen in Acute Diseases; Airs, Waters, and Places; Fractures; Joints; Wounds of the Head; Ancient Medicine; Prognostics; and Prorrhethics. Hippocrates is best known for his careful clinical observations and for his reporting of his failures as well as his successes. The first printed complete edition of the works of Hippocrates appeared in a folio at Rome in 1525. This Latin text was based on manuscripts in the Vatican. The first Greek edition was published by Aldus in 1526, and is one of the most beautiful productions of Hippocratic material. Other outstanding editions include Froben's printing at Basel in 1538 of Janus Cornarius's carefully edited text, the 1588 Venice edition by the Junta with both Greek and Latin texts, and the beautiful Vienna edition of 1743–1749. The 10-volume edition by Littré, which was originally published in 1839–1861 and reprinted in 1961–1962, is basic. English translations are available by Francis

Adams (first printed in 1849 and reprinted in 1964) and by W.H.S. Jones and E.T. Withington, in four volumes, in the Loeb Classical edition (1923–1931). The first French translation was done at Lyons in 1555, the first Spanish one in Madrid in 1757–1770, and the first German edition in Altenburg in 1781–1792.

While the Greek medical literature lies in the main stream of our own heritage, this was not the only area of such activity. India and China both made substantial contributions to the medical literature. Susruta wrote one of the major works in the Sanskrit literature, and one that is especially important in such surgical matters as extraction of cataract, caesarean section, lithotomy, and plastic surgery. Over 760 medicinal plants are mentioned. Charaka, another Hindu writer, produced a medical treatise around 400 B.C. This was translated into Arabic and Persian in the tenth century A.D., and an English translation was published in 1949 (six volumes).

Pien Ch'iao (Ch'in Yüeh), who flourished in the first half of the fifth century B.C., supposedly wrote the *Nan Ching*, a medical treatise of 81 chapters, in which he developed the theory of the pulse. This became one of the most popular Chinese medical works, has had many commentaries, and was translated into German. The *Nan Ching* was based in good part on an even earlier work, the *Huang Ti Nei Ching*, which was probably written about 1000 B.C. Chapters 1 to 34 were translated into English by Ilza Veith in 1949.

Among the Greeks that came after Hippocrates was, of course, Aristotle, whose dissections of animals added much to the basic medical literature. The best edition of his works was a Greek-Latin text in five volumes published in Berlin in 1851–1870. An English translation edited by J.A. Smith and W.D. Ross was published in 12 volumes by Oxford, 1908–1952. A son-in-law of Hippocrates, Polybos, wrote *On the Nature of Men* around 400 B.C., and this became the main source for the theory of the four humors. Diocles of Carystos, called the “second Hippocrates” in Athens, shortly thereafter wrote the first work entitled *Anatomy* and the first work on medical botany.

A pupil of Aristotle, Menon, wrote an important book in verse that summarized the pathological views of the predecessors and contemporaries of Hippocrates. A student's notebook based on this work and dating from about A.D. 150 was found in Egypt and provides an important link to a truer perspective of the Hippocratic doctrines.

Nacandros of Colophon in Ionia used both prose and verse for his works on drugs, poisonous animals, and prognostics. He was the first to speak of the therapeutic use of leeches. Aldus published his *Theriaca et Alexipharmaca* in Greek in 1499. A Latin translation appeared at Cologne in 1531 and a French translation came out in 1568. Another Greek writer on drugs, Servilius Damocrates of Athens (fl. A.D. 60–80), attempted to provide a safety feature in his prescriptions by couching them in iambic trimeters. In this way any careless changes

in the numbers made by the copyists could be detected. This can be looked on as an early form of the check digit used in some computer programs.

The works of the Greek medical writers, Erasistratus and Herophilos, of the Alexandrian School (flourished around 300 B.C.) were caught up in the destruction of the Alexandrian Library under Theodosius the Great. Some fragments of their texts and comments on their work have been preserved in the writings of Galen and others. Erasistratus was among the first physicians to discard the humoral theory, and his experimental work has led some to call him the founder of physiology.

Apollonios of Citium, around 100 B.C., wrote a commentary on Hippocrates' *On Articulations* that has survived in a ninth century A.D. manuscript illustrated with figures that probably date from even earlier times.

Specialization occurs in Greek times, and Demosthenes Philalethes (fl. A.D. 60) wrote an important work on ophthalmology that was a major source for many years. Manuscripts were still being made of this in the fourteenth century.

The work of Xenocrates of Aphrodisias appeared around A.D. 70. This was a major source for Pliny's *Natural History*, which had a profound and far-reaching effect in the medical literature as well as in many other areas.

At about this same time Pedacius Dioscorides, a Greek army surgeon, wrote his *materia medica*, which was to be widely used for 1500 years. This work, describing some 600 medicinal plants, survives in a beautifully illustrated manuscript written about 512 and preserved in the National Library at Vienna. The first Latin edition was printed at Colle in 1478, and Aldus produced the first Greek text in 1499. This is a typically beautiful Aldine production but is of great rarity. An Italian translation was printed in Venice in 1542, German in Frankfurt in 1546, and Spanish in Amsterdam in 1555.

The first major text in obstetrics and gynecology was written by Soranus of Ephesus (A.D. 98–138). His acute observations and excellent teaching ability are evident in his accounts of obstetric manipulations and of infant hygiene and nutrition. His writings were later the sources for Rösslin's *Rosengarten* (1513) and Raynalde's *Byrthe of Mankynde* (1545). Soranus gave sources for his quotations, one of the first writers to do this with any consistency. Most of his works have been lost, although his text on gynecology has survived in Greek and an English translation was made by Temkin in 1956.

LATIN AND GREEK MANUSCRIPTS

The earliest scientific medical work to be written originally in Latin was the *De Re Medicina* of Aurelius Cornelius Celsus, a layman. The eight books making up this compilation were based on Hippocrates. It became one of the most frequently produced medical publications,

although it was barely noticed either by Celsus's contemporaries or the medieval commentators. The first printed edition appeared in Florence in 1478. Over 105 editions of Celsus have been printed. In addition to the Florentine, which is quite rare, important editions were produced in Milan in 1481, in Venice in 1524, by the Aldine press in 1525, and by the Elzevirs in 1657. The Loeb Classical Library published a three-volume English translation by Walter George Spencer in 1935–1938.

Pliny produced his *Historia Naturalis* in the first century A.D. Three books of this deal with medicine. Many manuscripts and early printings of this exist. The first printed edition appeared in Venice in 1469.

Galen, second only to Hippocrates among the authors of Greek medical literature, lived from A.D. 130–200. Galen's writings—nine books on anatomy, 17 on physiology, six on pathology, 14 on therapeutics, and 30 on pharmacy—provided standards in medicine for over a thousand years. Much of his work has not been available in English until recently. In fact, his *On Medical Experience* was unknown until 1931 when a manuscript of it was found in Istanbul and translated from the Arabic into English by Walzer (1944). A major English translation was made by Margaret T. May of his *On Usefulness of the Parts of the Body*, which was published in two volumes in 1968. Galen's other major anatomical work, *On Anatomical Procedures*, has been translated in two parts, the first by Singer in 1956 and the second by Duckworth in 1962. Rudolph Siegel has translated substantial portions of Galen's work in his volumes, and Paul W. Harkins translated *On the Passions & Errors of the Soul* in 1964. Much of Galen's work was preserved only through the medium of Arabic translations.

The first Latin edition of Galen's works to be printed was done in 1490 in Venice where the first Greek edition, in five volumes, was printed by Aldus in 1525. Conrad Gesner did a Latin translation in 1562. The best text was the Greek-Latin edition done by Kühn at Leipzig (20 volumes, 1821–1833). A reprinting began in 1964.

China continued to produce medical works of importance. The most famous was the *Shang Han Lun* (*Essay on Typhoid*) published in A.D. 217 and written by Chang Chung-ching, the "Hippocrates of China." Hua T'o (Yüan), ca. A.D. 190–265, wrote medical and surgical works that were also translated into Japanese. Huang Fu (Shih An), ca. 215–282, wrote widely, and his most famous treatise, *Chia-i-Ching*, on acupuncture, became the basis for all future works on this subject.

From the fourth through the seventh centuries a number of Greek compilers performed valuable services for the medical literature by gathering many manuscripts and commenting on them. These compilations provide us today with our only knowledge of many writers.

Oribasius (325–403) was the first of these. His two encyclopedias preserved much material that would otherwise be lost. A Latin edition of his works was printed at

Basel in 1557. The best edition is a French translation by Bussemaker and Daremberg (six volumes, Paris, 1851–1876). Oribasius carefully explained Galen's doctrines, preserved many of his writings, and did much to establish the supremacy of Galen in the medical literature for the next thousand years. Oribasius also wrote a four-volume work, *Euporista*, designed to present reliable medical information to the laity.

Aëtius of Amida (502–575) compiled the *Tetrabiblion*, which contains many valuable quotations. Froben printed a Latin translation by Montanus and Cornuarius at Basel (1533–1535, 1542).

Alexander of Tralles (525–605), another compiler, included some of his own observations on worms and vermifuges in his compilations, and so could be called the first parasitologist. The first printed edition appeared at Lyons in 1504. The best text is the Greek-German edition produced by Puschmann at Vienna (1878–1879). This was reprinted at Amsterdam in 1963.

Paul of Aegina (625–690) wrote an *Epitome* in seven books that included many of his own valuable writings on lithotomy, tonsillectomy, amputation of the breast, and the first clear description of lead poisoning. The Aldine Press produced a Greek edition in 1528, and a Latin translation was done in Paris in 1532. Francis Adams, under the auspices of the Sydenham Society, made an English translation in three volumes (1844–1847).

Medical writing appeared in Spain in the seventh century: three books of Isidore of Seville's massive encyclopedia dealt with medical subjects. Shortly thereafter in England the Venerable Bede wrote on bloodletting and the rehabilitation of sufferers from aphasia.

ARABIC WRITINGS, SCHOOL OF SALERNO, AND LATE MANUSCRIPTS

Major developments in the Middle Ages took place in the Arabic literature and at the School of Salerno just south of Naples. The ebb and flow of religious and military struggles had led to the establishment of a medical school at Jundishapur in Persia in the middle of the eighth century. The need for texts produced both translations and original writings. Hunain ibn Isabq Al-Ibadi made translations of Hippocrates, Galen, Oribasius, and others from Greek into Arabic and so helped to preserve the works of these writers during the destructive times that had settled on Europe. Among the Arabic authors to make substantial contributions to the literature were Rhazes (860–932) who gave the first accurate descriptions of smallpox and measles. His major work, the *Al-Hawi* or *Continents*, was compiled posthumously from notes made by his students. The ninth book of this was used as a basis for therapeutics for several centuries; one of the revisions of it was done by first printed edition, by Britannicus at Brescia in 1486, ranks not only as an important work in the history of the

medical literature but also as (at 22 pounds) the heaviest of the medical incunabula.

The location of pieces of the medical literature can sometimes come as a surprise. Two leaves of a twelfth-thirteenth century manuscript of Rhazes were found in the twentieth century by J. Christian Bay as he was preparing a sixteenth century volume for rebinding. The Rhazes material had been incorporated in the covers of the newer work.

The “Prince of Physicians,” Avicenna (980–1037), included many of his own original observations in his major work that codified all medical knowledge known at that time. This publication, the *Canon*, became the standard text for many years and was used in European and Asian universities for five centuries. The original Arabic version was printed at Rome in 1593, the first of many Latin editions was printed in 1472, and an edition in Hebrew appeared at Naples in 1491. However, much of Avicenna's work has not been printed, and very little is available in English.

The leading textbook of surgery during the Middle Ages was the *Altastrif* written by Albucasis (936–1013), a native of Zahra near Cordova. This was based on the work of Paul of Aegina. An excellent Arabic-Latin edition was done by Channing at Oxford (two volumes, 1778). Portions of this have been translated into English by Spink (1937).

Another major contributor growing from the Arabic conquests was Moses Maimonides (Rabbi Moses ben Maimon) who lived from 1135 to 1204. Born at Cordova, Maimonides became court physician to the sultan at Cairo. Maimonides's *Aphorisms* was his most popular medical work, but he wrote on many subjects including poisons, personal hygiene, and asthma. His list of drug names in Arabic, Greek, Persian, Berber, and Spanish was of great importance. The Arabic manuscript for this list was not discovered until 1932. Maimonides did his writing in Arabic but the books were immediately translated into Hebrew. English translations of his works by Munter, Rosner, and Danby have been appearing since the 1950s.

The preservation of Greek and Latin works in Arabic was an outstanding contribution of this period. The gradual retranslation back into the original languages began as early as the eleventh century. Constantinus Africanus, a native of Carthage working at Salerno and Monte Cassino, translated many of the manuscripts of Hippocrates and Galen out of Arabic and also helped to make the works of Rhazes and Avicenna known to the physicians of Western Europe. Other well-known translators of a slightly later date were Gerard of Cremona and Michael Scotus.

The School of Salerno, which flourished between 1050 and 1200, not only provided a home for many translators such as Constantinus but also itself contributed important works to the literature. The poetic handbook of domestic medicine known as the *Regimen Sanitatis Salernitanum* is the most famous of these; over 100 manuscripts of this exist in European libraries and more than 500 editions

have been printed. Many of the major works produced at Salerno are contained in the twelfth-century Breslau Codex, which was discovered in 1837.

A new form of medical literature, “consilia,” sprang up in the fourteenth and fifteenth centuries. These took the form of medical casebooks or clinical records. Some of these were written in the form of letters from a physician to his student or colleague. The consilia of Alderotti, a thirteenth-century physician of Bologna, became widely known.

In the three centuries immediately preceding the invention of printing from movable metal type, several manuscript works became especially well known. Lanfranc of Milan completed his major text on surgery in 1296. This was translated into English about 1380 and became the first important surgical work to appear in that language. The first printed version was supposedly done at Venice in 1490 but no copy of it has been found. However, a French translation at Lyons in the same year does exist. An English edition was printed in 1565. Other important surgical works were written by Theodoric, Henri de Mondeville, and Guy de Chauliac. Mondeville incorporated illustrations of separate organs and full-length pictures in his manuscripts.

Mondino de Luzzi of Bologna wrote a practical manual of anatomy that was completed in 1316 and served as the only textbook of anatomy for use in medical schools until well into the next century. The first printed edition appeared at Pavia in 1478. Over three dozen editions and translations of this popular work were eventually published. Charles Singer produced an English translation in 1925.

One of the most popular surgical works of this period was the *Chirurgia Magna* written in 1363 by Guy de Chauliac. The Bibliothèque Nationale alone has 14 manuscript versions; 43 French editions, 16 Latin, five Italian, and four Dutch editions are known. It was also translated into English, German, Italian, Spanish, Hebrew, Provençal, and Catalan.

Major medical writers in England included Gilbertus Anglicus (ca. 1166–1230), who had studied at Salerno, and John of Gaddesden (1280?–1361), who wrote the *Rosa Anglica*, *Practica Medicina a Capite ad Pedes* in 1314. When this was edited by Nicolaus Scyllatius Siculus in 1492 it became the first printed medical book by an Englishman. Many manuscript and printed versions of the *Rosa* still exist.

The first pharmacopoeia in the modern sense appeared in the middle of the fifteenth century. The *Compendium Aromatorium* by Saladinus de Asculo of Tarento, was used by apothecaries for centuries. It also served as a model for all of the early pharmaceutical textbooks.

EARLY PRINTED WORKS

With the invention of printing from movable metal type in the middle of the fifteenth century the medical literature

underwent a rapid and widespread growth, much more so than many other disciplines. The earliest example extant of such printed medical literature is the top half of a purgation calendar printed at Mainz in 1457. These calendars gave the best dates for bleeding and purging, were very popular, and were apparently worn out by their users. The Mainz Kalendar was printed with the same Gutenberg types used for the Thirty-Six Line Bible. It was discovered in 1803 and is now in the Bibliothèque Nationale.

Another popular form of the early printed medical literature was the “Pestblätter.” These tracts, giving advice on treatment of the plague, were issued throughout Europe; originals and facsimiles are housed in many current collections. The printed tracts are descended from a manuscript form, one of the earliest representatives of which was written by John of Burgundy in 1365.

A fascinating off-shoot of medical printing, in production approximately from 1493 to 1683, is known as the anatomical fugitive sheet. Manuscripts of a medical nature had gradually been making more use of illustrations in the centuries just before the modern type of printing started. When this much faster method of production became available a flood of these sheets, most of which were designed for the curious layman, poured from presses in many countries. These sheets were generally on good quality soft, rather thick paper, and measured about 30 × 40 cm (some were substantially larger). A central anatomical figure was usually surrounded by a descriptive text and often a decorative border. The illustrations were done either by woodblock or copperplate. The earliest sheets were printed in black; colors were soon introduced. The first texts were generally in Latin, but vernacular versions rapidly appeared. Simple skeletons formed the earliest subjects (frequently in the rather distorted, almost frog-like, patterns of the manuscripts). There were sheets of a single male or female figure, of the “Adam and Eve” plates, and then of the *Tabulae* originally produced by Vesalius in 1538. The Vesalian sheets were plagiarized and edited at a great rate.

Most of these fugitive sheets were single, although some consisted of two sheets with the second containing most of the descriptive text. The Vesalius set ran to six sheets, and a variation on this by Walter Ryff was composed of 10. Superimposed flaps were used to show different levels of the viscera. A pregnant uterus was frequently one level of these flaps, and the fetus in these representations was often in the cowering “see no evil” position. As this form of publication became more sophisticated, as many as a dozen or more such flaps would be used. These reached their peak in the work of Remmelin in the seventeenth century.

Anatomical illustrations also appeared in the early printed medical books. A major example is found in Johann de Ketham’s *Fasciculus Medicinae*. This collection of short treatises was first printed in Venice in 1491 with rather primitive woodcuts. However, the beautiful

figures in the 1493 edition were probably done directly from a dissection. Ultimately 33 editions were published, and it was translated into several languages. Singer translated it into English in 1925 and a facsimile of the 1493 edition was printed in 1963.

The book usually referred to as the first printed medical book is really a general encyclopedia with a chapter on medicine. Adolf Rusch of Strassburg printed the *De Sermonum Proprietate, seu de Universo* of Rabanus Maurus probably in 1467. Book 18, Chapter 5, deals with medicine; it was translated into English by Jessup in 1934. The earliest printed medical books included the following titles. The “*Speculum Vitae Humanae*” by Rodericus Zamorensis was printed by Sweynheym and Pannartz at Rome in 1468. Pliny’s *Historia Naturalis* was printed by Johannes de Spira in Venice in 1469, and in Rome in 1470 by Sweynheym and Pannartz. Gulielmus de Saliceto, professor of surgery at Bologna in the middle of the thirteenth century, was especially popular in medical incunabula with several of his works appearing in the 1470s. Two editions of his *De Salute Corporis* were printed in 1470. Albucasis’ *Liber Servitoris*, translated by Simon Januensis, was printed by Nicolas Jenson in Venice in 1471. In that same year Jenson also printed one of the most popular works from the School of Salerno, Nicholas’s *Antidotarium*. The *Opera* of Joannes Mesue, Junior, was produced in two versions by Clemens Patavinus at Venice in 1471.

In April 1472 the first medical work in German, the *Regimen Sanitatis Deutsch*, was printed by Johann B  mler. This was translated into many languages and appeared in about 250 editions. The first printed medical book in Italian was by Gulielmo de Saliceto, *La Ciroxia Vulgarmento Fata*, done by Filip di Pietro at Venice in 1474. This is also very likely the first printed work on surgery. The first French book, as might be expected, was Guy de Chauliac’s *Chirurgia Magna*, printed at Lyons in 1478. Pediatrics achieved its first printed work in the form of the *De Infantium Aegritudinibus et Remediis* by Paolo Bagellardi, done at Padua in 1472. The first work in ophthalmology was published a year earlier in Ferrara, *De Oculis Eorumque Aegritudinibus et Curis* by Benvenuto Grassi. Casey Wood translated this into English in 1929.

The first practical medical dictionary to appear in print was the *Aggregator Paduanus de Medicinis* by De Dondis done by Rusch in 1480, although fragments exist from Simone de Cordo’s *Synonyma Medicinae seu Clavis Sanationis* printed at Ferrara in 1471 or 1472.

The John Rylands Library in Manchester has the only known copy of the first medical book printed in England. This was written by Canutus (Knutsson), Bishop of Arusiens, and is entitled *A Litil Boke the which Traytied and Reherced many Gode Things necessities for the...Pestilence*, and published by William Machlinia at London in 1485. Machlinia produced new versions in 1488 and 1490, the latter claiming some fame as being

the first English book with a title page. Wynkyn de Worde published an edition of this in 1510. William Caxton printed the second English medical book, *Governayle of Helthe*, in 1489, and de Worde later reprinted this.

The rapid spread and increasing numbers of medical books produced by the development of modern printing makes it necessary from now on to be much more highly selective.

The earliest printed herbal, the grandfather, so to speak, of a major class of medical works, was the *Herbarium* of Apuleius Barbarus (the “Pseudo-Apuleius”) printed at Rome in 1481. The contents of this herbal dated back to the fourth century. Gunther produced a modern English translation at Oxford in 1925. A manuscript herbal of considerable interest, written by the Aztec Indian physician Martinus de la Cruz, and translated into Latin by another Aztec, Juannes Badianus, in 1552, is housed in the Vatican Library. A beautiful color facsimile, with translation into English by Emily Walcott Emmart, was published at Baltimore in 1940.

Many intriguing medical works called “olas” were written on the leaves of talipot palms in Ceylon and neighboring areas between 1400 and 1750. Most of these contained prescriptions, some were primarily magical, and a few had illustrations.

THE SIXTEENTH CENTURY

Vesalius was the earliest outstanding contributor to the medical literature after the invention of modern printing. He performed his first public anatomy at Bologna in 1540 (when he was just 26 years old), and the notes made on that occasion by one of his students, Baldasar Heseler (five or six years older than his teacher), were translated into English by Eriksson and published at Stockholm in 1959. Vesalius’s major work, *De Humani Corporis Fabrica Libri Septem*, was printed by Oporinus at Basel in 1543. This monumental work, the first scientific text in anatomy, is one of the classics in the development of the medical literature. Vesalius based his work on his own dissections, and questioned many of the statements made by Galen that had been widely accepted and used for almost 1500 years. No English translation of the complete *Fabrica* has yet appeared, although a handsome facsimile was produced at Brussels in 1963. The “muscle men” plates by Calcar, a pupil of Titian, are works of both art and science. An epitome was issued the same year, and a corrected and expanded edition of the *Fabrica* came out in 1555. An English translation of the *Epitome* by Lind was published in New York in 1949.

The Vesalian plates were plagiarized far and wide. Thomas Geminus, both a surgeon and an engraver, persuaded Henry VIII to underwrite the publication of his *Compendiosa*, which was based on Vesalius. The copper plates, engraved by Geminus, marked this as the first

illustrated textbook published in England. Nicholas Hyll printed it at London in 1545, an English translation by Nicholas Udall appeared in 1553, and Charles O'Malley produced a facsimile of Udall's translation in 1959.

Important contributions to the publication of anatomical information were made by Eustachius in his *Opuscula Anatomica* printed at Venice in 1564. He had completed 38 copper plates for another book, but was prevented by death from publishing it. These plates disappeared for 150 years; they were finally discovered by Lancisi and published as the *Tabulae Anatomicae* at Rome in 1714.

Eucharius Rösslin, a physician at Worms and Frankfurt-on-Main, compiled the first printed textbook for midwives from the earlier work of Soranus of Ephesus. This *De Swangern Frauen und Hebammen Roszgarten*, illustrated by woodcuts, was printed in 1513 at Strassburg. It became widely used, went through at least 40 editions, and was translated into Dutch, Czech, French, Latin, and English.

The first medical book by a medical man to be originally written and printed in English was the *Breviary of Health* by Andrew Boorde. This was published by Middleton at London in 1547, and five more editions had appeared by the end of the century. The *Breviary* was an important contribution to family medicine despite the facts that Boorde was the model for the term "A Merry Andrew," left as one of his aphorisms the true statement, "Myrth is one of the chiefest thynges in Physicke," and died in the Fleet Prison.

In 1530 appeared the major poetic contribution to the medical literature, Girolamo Fracastoro's *Syphilis, sive Morbus Gallicus*. This was printed by do Sabbio at Verona, and went through over 100 editions, being translated into Italian, English, French, German, Spanish, and Portuguese. Fracastoro's poem recognized the venereal cause of syphilis, gave the disease its name, and referred to mercury as a remedy.

The first major text in physiology, the *De Naturali Parte Medicinae* by Jean Fernel, was printed at Paris in 1542. The original edition is rare but later editions from France and Italy are more common. Fernel also wrote important contributions on pathology and therapeutics, as well as mathematics and astronomy.

An original thinker by the name of Philippus Aureolus Theophrastus Bombastes von Hohenheim, better known as Paracelsus, shot across the medical scene in the first half of the sixteenth century. He did much to change the emphasis in medicine to a more chemically oriented viewpoint, and advanced the availability of the medical literature by writing in his native German rather than Latin. Ambroise Paré, the great surgeon, was increasing his accessibility in the French medical literature. Until medical works became available in the vernacular, the spread of medical knowledge was considerably limited.

A German work holds an important place in the development of the ophthalmological literature. Georg

Bartisch, the founder of modern ophthalmology, had his *Ophthalmouoleia, das ist Augendienst* published at Dresden in 1583. This book, well-illustrated with woodcuts, makes use of the overlays found in some of the anatomical fugitive sheets. A facsimile was issued in 1966.

Paré, who made his name as a military surgeon and the royal surgeon to four kings of France, wrote up his discovery of a new method of treating wounds (rather than the previously used boiling oil) in 1545. This went through several editions and was translated into Dutch and English. A handsome folio edition of his complete works appeared at Paris in 1575. A facsimile of the best French edition (Lyons, 1585) was reprinted in 1962. Paré's works were translated into Latin (1582), marking acceptance by the conservatives, and into English, by Thomas Johnson, in 1634. German, Dutch, and Japanese translations were also published. Several of Paré's works contain striking illustrations of surgical instruments and prostheses.

The literature of plastic surgery received its first major contribution from the pen of Gaspare Tagliacozzi of Bologna. His *De Curtorum Chirurgia per Insitionem*, published at Venice by Bindoni in 1597, has become a classic. This was issued in a pirated edition the same year. Despite the importance of Tagliacozzi's work, both Paré and Fallopius spoke out against him, and the Church dug up his body and reburied it in unconsecrated ground.

Although there was an increasing number of original contributions by contemporary authors, the classical writers were not forgotten. The first English translation of Hippocrates, done by Peter Lowe, was published in 1597. An excellent Latin translation of Hippocrates' *Aphorisms* was produced by François Rabelais.

The first book on pediatrics to be written in English was published in 1545 when *The Boke of Children* by Thomas Phaïre appeared as an addendum to an English translation Phaïre had made of the *Regimen Sanitatis Salerni*. Many later editions of the *Boke* were published, and it was reprinted in 1955.

In bringing the medical literature of the sixteenth century to a close, we may note the earliest medical works printed in America. The first of these, Francisco Bravo's *Opera Medicinalia*, was published in Mexico in 1570. Only three copies of this are now known. The *Summa y Recopilacion de Cirugia* by Alphonso Lopez de Hinozoso, the first important surgical work produced in the Americas, was published in 1578 with a second edition in 1595. The first text in anatomy was Farfan's *Tractado Brebe de Anothomia y Chirurgia*, printed in 1579.

THE SEVENTEENTH CENTURY

The outstanding medical book of the seventeenth century, and one of the classics of all time, was William Harvey's *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*, often called simply the *De Motu Cordis*. This

small volume, in which Harvey announced his discovery of the circulation of the blood, was published by William Fitzer at Frankfort in 1628. A few copies were printed on heavy paper, and these have become top prizes in the book-purchasing efforts of both institutions and individuals. Important editions were produced at Padua in 1643 and 1689; Rotterdam in 1648, 1654, 1660, 1671; London, 1660; Bologna, 1697; Leyden, 1736; Glasgow, 1751; and Edinburgh, 1824. Dutch and English (1653, 1673) translations have been made. A modern translation by Kenneth Franklin came out in 1957. Harvey is one of the few medical authors who has not only had a bibliography of his works compiled (by Geoffrey Keynes) but has had it go into a second edition. Several manuscripts important to Harvey's work have recently been translated and printed by Gweneth Whitteridge, Kenneth Franklin, and others.

The "first of the great English surgeons," Richard Wiseman, had his *A Treatise of Wounds* published in London in 1672. Copies of this are in the British Museum and the National Library of Medicine. Wiseman's *Severall Chirurgicall Treatises*, published in 1676, another important work, went through many editions.

The "English Hippocrates," Thomas Sydenham, emphasized careful and detailed observations. Among his outstanding contributions to the medical literature were his work on gout, *Tractatus de Podagra et Hydrope*, published at London in 1683, and books on hysteria and fevers. His complete works, published in Amsterdam (1683) and London (1685), went through many editions and translations. The best English translation was done by R.G. Latham in 1848–1850. Sydenham's medical notes and observations were printed at Oxford in 1845 as *Anecdota Sydenhamiana*. Sydenham wrote his works in English and had them translated into Latin so that they could achieve a wider circulation. Several of his manuscripts have recently been described and work is continuing on these, especially on the relationships between Sydenham and John Locke.

One of the most fascinating English medical authors of this period was Nicholas Culpeper. His writings were especially popular with apothecaries and laymen although he was a classical scholar. The first, *Pharmacopoeia Londinensis*, was published in 1618 by the College of Physicians (a facsimile was produced in 1944). Since this was in Latin, the information it contained was not accessible to most people. Culpeper translated it into English as *A Physicall Directory* in 1649, and aroused the unforgiving wrath of the College. When the second edition came out in 1650, Culpeper translated it also (1653), and this was rapidly spread both legally and piratically over many countries. An edition printed in Boston in 1720 probably has title to being the first full-length medical work to be produced in the colonies. Culpeper's *A Directory for Midwives*, London, 1651, was so popular that by 1777 it had been reprinted 17 times.

In 1651 Francis Glisson produced his *De Rachitide, sive Morbo Puerili, qui Vulgo The Rickets Dicitur* in London, and Culpeper promptly translated it into English. Culpeper's most famous work was probably his herbal, *The English Physitian*, which appeared in three editions its first year (1652); 14 more came out before 1700, and over 100 editions have been printed.

Culpeper's appeal through his herbal, anti establishment translations, and lively style has been long lasting. As recently as 1910 he was the subject of a story by Rudyard Kipling.

The seventeenth century saw the first major work on vital statistics by John Graunt, Edmund Halley, and Sir William Petty. The Italian, Sanctorio Sanctorius, wrote up his careful studies on the physiology of metabolism based on experiments on himself using a steelyard balance. His *De Statica Medicina*, first published in Leipzig in 1614, went through at least 20 editions and several translations. In his commentary on the first book of Avicenna's *Canon* (1625), Sanctorius described his development and use of a thermometer and a pulse-clock in both text and picture.

The first major work in medical jurisprudence was published in a nine-volume set, 1621–1661, at Rome and Amsterdam. The *Quaestiones Medico-Legales* was written by Paolo Zacchias, a Papal physician, who may be looked on as one of the founders of this field.

Another "founder" of a field was active appeared at the same time. In 1623 the first important work on tropical medicine appeared, the *Tratado de las Siete Enfermedades* by Alexo de Abreu, printed at Lisbon. Abreu's text contained the first accurate descriptions of yellow fever and amebic hepatitis.

Although Francis Glisson had been a member of a committee selected to write a book on rickets, most of the medical literature produced up to this time had been the work of individuals (as Glisson's book eventually turned out to be). In the seventeenth century scientists began to assemble in societies for the purpose of presenting papers and exchanging information. This development had a profound and far-reaching effect on the production of medical literature by giving birth to the concept of important, stable, scientific periodicals.

The Royal Society of London was formally organized in 1660, and began publication of its *Philosophical Transactions* on March 6, 1665. This journal, still being published, has had the honor of printing many substantial contributions to the medical literature by such authors as Lower, Hooke, Leeuwenhoek, Cowper, Cheselden, Priestly, Hunter, and many others, as well as important work by relatively unknown individuals (e.g., smallpox inoculation by Timoni and Pylarini). Over 80 papers printed in the *Philosophical Transactions* have merited a place in the *Garrison-Morton Bibliography* of contributions to the history of medicine.

Other societies in different countries were also formed at this time. The Collegium Naturae Curiosorum was founded in Germany in 1651 and produced the first volume of its *Miscellanea Curiosa sive Ephemeridium Medico Physicorum Germanorum* in 1670.

The earliest periodical with some medical material to be printed in France was the *Journal des Scavans*, which began on January 5, 1665, and is still being published. Nicolas de Blegny's *Nouvelles Découvertes sur Toutes les Parties de la Médecine* ran from 1679 to 1683; this was the first medical journal in the vernacular although it had a separate Latin version as well. Early medical periodicals in both the seventeenth and eighteenth centuries were often translated into other languages and had several editions of some or all of their volumes.

The first medical journal in English, *Medicina Curiosa*, had its first issue (of two) out on June 17, 1684. The only other English medical journal of the seventeenth century was the *Hippocrates Ridens*, which was born and died in 1686. The *Acta Medica et Philosophica Hafniensia* was printed in Denmark from 1673 to 1680.

Prior to the appearance of the periodical, current medical information was usually transmitted by letter. One physician would include clinical observations in a letter to a colleague who would then reply with comments and questions. A particularly important letter might be circulated by its recipient among his colleagues so that the information could reach a wider audience. This could in turn provoke additional letters back to the original writer.

Other manuscript sources of medical literature included student notebooks which were often retained by the graduate for later consultation while in practice. This was particularly true of the North American colonists who attended medical school in Great Britain or on the continent and returned to the colonies to practice. Some of these notebooks were indexed for easier location of information.

Manuscript compilations of prescriptions would also serve as medical works, especially in the absence of printed materials. These would sometimes be used both in the clinical work of the practitioner and as a textbook for his apprentices.

The North American colonies, later to become the United States of America, saw the first glimmerings of medical literature in the seventeenth century. The first such document printed in the colonies was *God's Terrible Voice in the City of London* by Thomas Vincent, an account of the plague in London in 1665. This 31-page booklet was printed at Cambridge in 1668 by Marmaduke Johnson. The American Antiquarian Society at Worcester has a copy.

The first piece of medical literature to be written and printed in this country was Thomas Thacher's *A Brief Rule to Guide the Common-People of New-England how to order themselves and theirs in the small pocks or measles*, printed by John Foster at Boston in 1678. This broadside, 17 × 12 5/16 inches, exists in only a single copy, which is at the

Massachusetts Historical Society. Benjamin Harris at Boston printed in 1694 a 129-page book by John Olwer entitled *A Present to be Given to Teeming Women*, a copy of which is held by the New York Academy of Medicine Library.

The first medical book published in South America was the *Dos Tratados*...by Francisco Figueroa, which appeared at Lima in 1616. No copy of this is known to exist today.

THE EIGHTEENTH CENTURY

One of the classic works appeared just before the end of the century. On May 14, 1796, Edward Jenner, a pupil of the great John Hunter, performed his first vaccination for smallpox. In June 1798 his classic, *An Inquiry into the Causes and Effects of the Variolae Vaccinae*, was printed in London by Low. Jenner described in it his 23 successful vaccinations, and also presented what is probably the first mention of anaphylaxis. A second edition was published in 1800 and a third in 1801. The book spread with almost the same rapidity as the disease itself. Ashley and Brewer reprinted the second edition at Springfield, Massachusetts, in 1802, and it appeared at Hanover (1799), Vienna (1799), Lyons (1800), Lisbon (1803), Pavia (1800), Haarlem (1801), and Madrid (1801). Later it reached Russia and Australia. Facsimiles have been printed at Milan (1923), Denver (1949), and London (1966). LeFanu produced a biobibliography of Jenner in 1951.

The outstanding English surgeon of this century was John Hunter, who was the one individual primarily responsible for placing the field of surgery on a scientific foundation. Hunter had been a pupil of both Cheselden and Pott, and had also studied with his older brother, William. John Hunter's most important book was his *A Treatise on the Blood, Inflammation and Gunshot Wounds*, first published in 1794 shortly after his death. This appeared in three more editions at London and in three editions at Philadelphia (the first by Thomas Bradford in 1796). French and German translations were produced before the end of the century.

Hunter's *Observations on Certain Parts of the Animal Oeconomy* was first published in 1786 with a second edition in 1813. A German translation appeared the same year. Hunter's detailed work in comparative anatomy and his own skillful operative procedures did much to raise the level of surgery.

His *A Treatise on the Venereal Disease* was published at London in 1786 and was most popular. Many editions and translations were produced.

Hunter not only had an excellent museum at his home but also his own private press, which produced his three most important books. He contributed to the periodical literature by papers in the *Philosophical Transactions*, but despite these publications much of his work was still in manuscript form at his death. His brother-in-law,

Everard Home, used this material for his own lectures and writings and then destroyed many of these valuable items.

John's older brother, William, made a major contribution to the medical literature in the form of the *Anatomia Uteri Gravid Tabulis Illustrata*, one of the finest anatomical atlases ever published. This was printed by John Baskerville in 1774 with 34 life-size copper plates and text in both Latin and English. The Sydenham Society reprinted it in 1851. Baskerville's only other medical publication had appeared 12 years earlier, *Virtues of Cinnabar and Musk Against the Bite of a Mad Dog* by J. Dalby.

The most outstanding eighteenth century English contribution to anatomy was made by the surgeon-anatomist William Cheselden in 1733 with publication at London of his *Osteographia, or the Anatomy of the Bones*. This covered all human bones as well as many of those in animals. Accuracy in the illustrations was achieved by using a camera obscura, devised by Cheselden. A facsimile of the *Osteographia* was printed in 1968.

Cheselden's *The Anatomy of the Human Body* was first published in 1713 when he was 25. Thirteen editions of this popular work had appeared by 1792; two American editions were published (1795 and 1806) and a German translation appeared in 1790.

Another anatomist who used careful measurements and mechanical assistance in the production of an atlas was Bernhard Siegfried Albinus, a pupil of Boerhaave. According to one report Albinus spent 24,000 florins on the illustrations (by Jan Wandelaar) for his atlases, the most important of which, *Tabulae Sceleti et Musculorum Corporis Humani*, was published at Leyden in 1747 with English editions in London, 1749, and Edinburgh, 1777.

Percival Pott made many substantial contributions to the surgical literature on ruptures, injuries of the head, fistulas, fractures, hydroceles, amputations, and cataract. These monographs frequently appeared in many editions and were often translated. Pott was also known for his work on curvature of the spine, cancer of the scrotum, and tumors.

James Lind produced his classic work, *A Treatise of the Scurvy*, in 1753. He described his experiments with citrus fruit in combatting this major problem for navies, explorers, and commercial sailors. Lind gave credit to previous writers on the subject, but it was his book and continued efforts that ultimately led to the control of this problem. The treatise was reprinted in 1953.

The first English text on dermatology, *De Morbis Cutaneis* by Daniel Turner, was printed in London in 1714. A pharmacological classic, William Withering's *An Account of the Foxglove and some of its Medical Uses*, was published at Birmingham in 1785. A facsimile edition was printed at London in 1949. The first English historian of medicine also appeared in this century, John Freind, whose 2-volume work, *The History of Physick; from the Time of Galen to the beginning of the sixteenth century*, was published at London in 1725–1726. Freind planned

out this history while he was in the Tower of London on a charge of high treason.

Another major work in the history of medicine appeared just 4 years later in France. Daniel LeClerc's *Histoire de la Médecine* ranks as the first major work in its field, one that is still consulted today. Although the first edition had appeared in French in 1696 and a translation into English was printed in 1699, the 1729 French edition is the best.

Kurt Sprengel's monumental 5-volume *Versuch einer pragmatischen Geschichte der Arzneykunde* was printed at Halle, 1792–1803. This has been a foundation stone for many later works in the history of medicine.

The outstanding physician of the eighteenth century, Hermann Boerhaave, published many works himself on clinical medicine, physiology, and chemistry, and substantial commentaries were produced by his students, especially Gerard van Swieten. Boerhaave's works, the most important of which were the *Aphorismi et Cognoscendis et Curandis Morbis in Usum Doctrinae Domesticæ* (first edition, Leyden, 1709) and the *Elementa Chemiæ* (first edition, Leyden, 1732), appeared in many editions and translations.

One of the all-time medical classics was published in 1761 at Venice. This was Giovanni Battista Morgagni's 2-volume *De Sedibus et Causis Morborum per Anatomen Indagatis Libri Quinque*. With this monumental publication Morgagni became the founder of modern pathological anatomy. Morgagni, professor of anatomy at Padua, correlated his findings at autopsy with the clinical records of some 700 patients. An English translation, done by Alexander in 1769, was reprinted in 1960.

A much smaller book, although also a medical classic of considerable proportions, came out the same year at Vienna. This was Leopold Auenbrugger's *Inventum Novum ex Percussione Thoracis Humani ut Signo Abstrusos Interni Pectoris Morbos Detergendi* in which he described his discovery of percussion. The *Inventum Novum* did not catch on until Corvisart produced his French translation in 1808, which led to percussion achieving its role of major importance. Forbes did an English translation in 1824; this was reprinted in 1936.

Medical publication began in earnest in the North American colonies that later became the United States. Pamphlets were an important feature of the early years of the century with the pamphlet war over smallpox inoculation taking place in the 1720s and 1730s and involving such individuals as Cotton Mather, Zabdiel Boylston, William Douglass, and Benjamin Franklin. Pamphlets also appeared on other communicable diseases and medical problems. Much of the early medical literature was printed in newspapers.

Cadwallader Colden wrote many pamphlets and texts, including his *Treatise on Wounds and Fevers* (printed about 1765—no copy is known today), which became a standard authority for many years. Thomas Cadwalader wrote his *Essay on the West-India Dry-Gripes* in 1745. It

described lead poisoning from rum. John Lining wrote important papers on metabolism and yellow fever.

In 1765 a classic work in medical education appeared, John Morgan's *A Discourse upon the Institution of Medical Schools in America*. This small book set the pattern for medical education in this country and had a considerable influence in other countries as well.

Four years later Samuel Bard wrote his *A Discourse upon the Duties of a Physician*, the first book on medical ethics in the North American colonies. It preceded Thomas Percival's important contribution by 25 years. Bard also wrote (1771) another major work, *An Enquiry into the Nature, Cause and Cure of the Angina Suffocativa* (one of the earliest accurate descriptions of diphtheria). The first colonial publication on medical history, Peter Middleton's *A Medical Discourse, or an Historical Inquiry into the Ancient and Present State of Medicine*, was published in 1769.

John Jones, drawing heavily on the writings of earlier English surgeons, produced the first surgical book published in the colonies in 1775. His *Plain Concise Practical Remarks on the Treatment of Wounds and Fractures* went through four editions and was the standard guide used during the Revolution.

One of the physicians who signed the Declaration of Independence, Benjamin Rush, was a prolific contributor to the literature of medicine and several other fields. Of importance were his *An Account of the Bilious Remitting Yellow Fever* (1794) and *Directions for Preserving the Health of Soldiers* (1778).

Two major medical works by laymen appeared in the last decade of the century. One of these, Mathew Carey's *A Short Account of the Malignant Fever, lately prevalent in Philadelphia* is an important description of yellow fever that was frequently reprinted and was translated into French and German. The other, a 2-volume set, was Noah Webster's *A Brief History of Epidemic and Pestilential Diseases*, 1799.

The first medical publication in Canada was the *Direction pour la Guérison du Mal de la Braie St. Paul*, published at Quebec in 1785, and the earliest general medical treatise produced in the Americas was Juan Manuel Venegas' *Compendio de la Medicina: ó Medicina Practica* from Mexico in 1788.

Books on home medicine were produced in the colonies just as they were in many other areas of the world. The first completely American offering was Dr. John Tennent's *Every Man His Own Doctor: or, the Poor Planter's Physician* (1734), which went through several editions and was widely used. Popular also were colonial reprints of Culpeper's *The English Physician* (Boston, 1708) and William Buchan's *Domestic Medicine* (over 30 American editions between 1771 and 1815).

The physician, in the early days of the United States, who wanted to write an article for publication in a medical journal had to look either outside the country or to a

nonmedical journal. England and France were favorites among the foreign countries. In fact it was a translation of a French medical journal, *Journal de Médecine Militaire*, whose first volume was published in New York around 1790 as the *Journal of the Practice of Medicine and Surgery and Pharmacy in the Military Hospitals of France* that has a tenuous claim to being the first medical journal published in the United States. Among the nonmedical journals in the United States favored by physicians for their medical articles were the *Memoirs of the American Academy of Arts and Sciences*, *American Museum*, *Philadelphia Monthly Magazine*, and the *Royal American Magazine*.

The first truly indigenous American medical journal was the *Medical Repository* whose first issue appeared on July 26, 1797. This was printed in New York by T.&J. Swords, and edited by Samuel Latham Mitchill, Edward Miller, and Elihu Hubbard Smith. This quarterly journal, the brainchild of Smith, the youngest of the three, met with immediate success and continued publication through volume 23 for 1824. Important articles that appeared in the *Medical Repository* included John Otto's "An Account of an Hemorrhagic Disposition Existing in Certain Families" [6, 1–3, (1803)], the first (American) description of hemophilia, and John Stearn's report of the first use of ergot in childbirth [2d Hexade, 5, 308–309 (1808)]. Outstanding authors whose articles were printed in these pages also included Philip Syng Physick, Benjamin Rush, Benjamin Waterhouse, and Noah Webster.

Transactions of various medical societies appeared sporadically in Europe. Early British medical journals (strictly speaking) included the *Foreign Medical Review* (1779–1880) and the *London Medical Journal* (1780–1800). The first substantial representative of this group was the *Medical and Physical Journal of London* (a continuation of the *Medical Facts and Observations*), which lived from 1799 to 1814. Much of its content consisted of translations and comments on articles from foreign journals.

The first major French medical journal was *Le Journal de Médecine, Chirurgie et Pharmacie*, which was published from 1754 to 1794 and 1801 to 1817. The *Gazette de Médecine* appeared under a variety of titles from 1761 until 1792. The *Gazette de Santé* began in 1773 and continued until 1829 when it became the *Gazette Médicale de Paris*. The *Journal General de Médecine, de Chirurgie et de Pharmacie* ran from 1796 to 1830.

Germany's first medical journal, from Leipzig, was the *Deliciae Medicae et Chirurgicae* which began in 1703 but lasted only until 1705. The *Natur und Medizin Kunst und Literature Geschichte* was published at Breslau from 1717 to 1729. The first major German medical journal was the *Acta Medicorum Berolinensium* which ran from 1717 to 1731. The first surgical journal to appear in Germany was Richter's *Chirurgische Bibliothek* (1771–1797). A semi-weekly journal, Hartenkeil's *Salzburger medicinisch-chirurgische Zeitung*, had enough material to keep going

from 1790 to 1842. The first established journal in medical history was edited by the scholarly Sprengel; the *Beiträge zur Geschichte der Medicin* lasted from 1794 to 1796.

The first major medical journal produced in Italy was the *Giornale per Servire alla Storia Ragionata della Medicina di questo Secole* which was printed in Venice from 1783 to 1790.

THE NINETEENTH CENTURY

Among the English medical books of this century to make a lasting impression on the medical literature must certainly be counted Henry Gray's *Anatomy, Descriptive and Surgical*. The first edition of "Gray's" was published in 1858, just three years before the author's early death from smallpox at 34. John W. Parker & Son published the first two editions (the only ones seen by Gray), and Henry Carter drew the illustrations. The first American edition was published in 1859, and the two countries have regularly produced separate editions since then (current editions, both for 1973, are the thirty-fifth in England and the twenty-ninth in the United States.)

One major feature of the nineteenth century was the appearance of the specific monograph, a trend which has increased in the present. An outstanding example of this was James Parkinson's *An Essay on the Shaking Palsy*; the original account of this eponymous disease was published by Whittingham and Rowland in London in 1817. The American Medical Association printed a facsimile in honor of the book's centennial, and Dawsons printed another facsimile in 1959. This essay has been twice reprinted in the journal literature (1922 and 1937–1938), and a German translation appeared in 1912.

A good example of the growing emphasis on journal publication is presented by the career of Sir James Paget who died in 1899. His name is memorialized in two diseases, and both of the original descriptions appeared not in book form but in journal articles. "On Disease of the Mammary Areola Preceding Cancer of the Mammary Gland" was printed in *St. Bartholomew's Hospital Reports* in 1874. "On a Form of Chronic Inflammation of Bones (Osteitis Deformans)" appeared in the *Medico-Chirurgical Transactions* in two papers (1877 and 1882). The *Reports* from St. Bartholomew's are an outstanding representative of this form of medical literature. Seven volumes of Paget's manuscript casebooks, another important facet of the literature, are in the Medical College Library at Bart's.

The French Revolution held up the publication of Philippe Pinel's *Traité Medico-Philosophique sur l'Aliénation Mentale ou la Manie* from 1792 until 1801. When this classic was finally published it created a great impetus for improvements in the treatment of the insane. An English translation appeared in 1806.

The invention of the stethoscope not only led to Laennec's *De l'Auscultation Mediate* in 1819, one of the most influential books of the century, but it also became the first "give-away" gimmick to accompany the sale of a book. Laennec's set (the first edition was in two volumes) had four more French editions, two printings in Belgium, seven English editions (the first in 1821), four printings in the United States (the first two in 1823), three German editions, and an Italian edition. The original French version was reprinted in 1962.

Claude Bernard, the founder of experimental medicine, published many of his important research reports in the burgeoning journals, but his *Introduction a l'Étude de la Médecine Experimentale*, first published at Paris in 1865, probably ranks as one of the most stimulating works in the medical literature. This edition was reprinted in 1949, and an English translation was produced in 1927.

The founder of scientific medicine in Germany was Johannes Peter Müller who, while primarily a physiologist, also had substantial interests in biology, comparative morphology, and pathology. Müller's two-volume *Handbuch der Physiologie des Menschen für Vorlesungen* (Coblenz, 1834–1840) was translated into both French and English. He founded the *Archiv für Anatomie, Physiologie, und wissenschaftliche Medicin* in 1834, a respected vehicle for many important papers over the years.

The most important German work on the history of medicine yet produced was written by Heinrich Haeser. The first edition of his *Lehrbuch der Geschichte der Medicin und der Volkskrankheiten* was published at Jena in 1845, and a three-volume third edition came out in 1875–1882.

The age of modern medicine was ushered in by *Die Cellularpathologie* of Rudolph Virchow in 1858. This was reprinted in 1966 and was translated into English (1860) and French (1861). Virchow, who was active in politics, anthropology, and history as well as medicine, was the founder of the *Archiv für pathologische Anatomie*, still known as *Virchow's Archiv*.

As a final example of the German medical literature of the nineteenth century the pioneering work of Wilhelm Conrad Röntgen may be cited. Röntgen never even wrote a book on X-rays, and his classic contribution took the form of a 10-page article in a rather obscure journal. Reprints of this article (which first appeared in 1895) are among the most expensive (per page) items in the history of the medical literature.

One of the major Russian contributions to the medical literature, Pavlov's *Lectures on the Work of the Principal Digestive Glands*, was published (in Russian) at St. Petersburg in 1897. A French translation appeared in 1901 and an English version in the following year.

During the nineteenth century medical literature in the United States was blossoming quickly and in many areas. Caspar Wistar wrote the first text in anatomy, the

two-volume *System of Anatomy*, which was published in 1811–1814, Robley Dunglison's textbook of physiology came out in 1832. Benjamin Smith Barton's *Elements of Botany* (1812) was the first book on materia medica and therapeutics, and Jacob Bigelow's three-volume *American Medical Botany* (1817–1820) achieved a considerable renown.

The first general pharmacopoeia was produced by the Massachusetts Medical Society in 1808, and 12 years later—also in Boston—appeared the first pharmacopoeia of the United States. The first Dispensary was published in 1833. The first substantial textbook of surgery was John Syng Dorsey's *Elements of Surgery* which came out in 1813.

Samuel Bard wrote the first textbook in obstetrics, *Compendium of the Theory and Practice of Midwifery*, in 1807. William Dewees has credit for the first United States texts in pediatrics (1825) and gynecology (1826).

The United States produced several classics in the literature of medicine during this century. In 1812 Benjamin Rush wrote his *Medical Inquiries and Observations upon the Diseases of the Mind*, which was not only the first American book in that field but also ranks as a landmark in its subject. In 1833 William Beaumont's *Experiments in Digestion* describing his investigations on Alexis St. Martin, the half-breed who miraculously survived a point-blank gunshot wound, was published. A British edition was published in Edinburgh in 1838. A German translation appeared in 1834. A facsimile of the 1833 edition was produced in 1929. In 1850 and 1854 the two volumes that composed Daniel Drake's *A Systematic Treatise, Historical, Etiological, and Practical, on the Principal Diseases of the Interior Valley of North America* were printed. In 1859 the first of six editions of Samuel David Gross' *A System of Surgery* was published, two volumes that did much to raise the level of American surgery both practically and in the eyes of the rest of the world. Among Gross's several monographs, the *Elements of Pathological Anatomy* and *A Practical Treatise on the Diseases, Injuries and Malformations of the Urinary Bladder, and Prostate Gland, and the Urethra* each went through three editions. William Osler published his *Principles and Practice of Medicine* in 1892, a textbook that set a standard for single-author works of this type. "Osler" went through many editions and was translated into a wide variety of languages.

The first United States medical journal after the *Medical Repository* was the *Philadelphia Medical Museum*, founded by John Redman Coxe, which ran through seven volumes between 1804 and 1811. This form of medical publication spread rapidly with the first medical journal appearing in Massachusetts in 1806 (*Medical and Agricultural Register*), in Maryland in 1808 (*Baltimore Medical and Physical Recorder*), in Ohio in 1822, Connecticut in 1823, and South Carolina in 1825. The first medical journal to appear west of the Mississippi was the *St. Louis Medical and Surgical Journal*, which began in 1843 and

continued for many years; and the first on the West Coast appeared in 1856, the *San Francisco Medical Journal*, which lasted for only one issue. The *Pacific Medical and Surgical Journal*, also from San Francisco, began in 1858 and was the first West Coast medical journal to be successful.

David Hosack and John W. Francis edited the *American Medical and Philosophical Register* through its four volumes (1810–1814), producing a second edition of the first volume, a practice that was fairly common at that time.

As medical journals became more accepted by both readers and authors as a means of transmitting medical information, important articles began to appear and important journals began long runs. Ephraim McDowell's report of his classic ovariectomy was printed in the *Eclectic Repository and Analytical Review* [7, 242–244 (1817)]. William Beaumont's first report on his studies of St. Martin's stomach appeared in the *American Medical Recorder* [8, 14–19 (1825)]. The author was erroneously given as Joseph Lovell, the surgeon general, but this mistake was corrected later in the same volume.

The *American Journal of Science*, which early contained much material of medical interest, was founded in 1818 by Benjamin Silliman and continues to this day.

The *Philadelphia Journal of the Medical and Physical Sciences* was founded by Nathaniel Chapman in 1820 as a patriotic response to Sydney Smith's slur earlier that year in the *Edinburgh Review*, "In the four quarters of the globe, who reads an American Book? or goes to an American play? or looks at an American picture or statue? What does the world yet owe to American physicians or surgeons?" This quotation appeared on the title page of Chapman's journal for several years, and the journal itself became in 1827 the renowned *American Journal of the Medical Sciences*, still published today. Its first editor, Isaac Hays, was one of the leaders in American medical journalism.

The early American medical journals contained many articles on meteorological conditions, fevers, and surgical procedures. Later, translations of articles (either summarized or complete) from the foreign journals often appeared. News items took up many pages, and editorials—sometimes of a vitriolic nature—showed the use of the medical journal as a platform for individual, institutional, or sectarian controversy.

The *Boston Medical Intelligencer* was founded in 1823 by Jerome F.C. Smith as this country's first weekly medical journal. In 1828 it was merged with the *New England Journal of Medicine and Surgery* (which had begun in 1812) to form the *Boston Medical and Surgical Journal*. This, one of the leading medical journals in the country, changed its title in 1929 to the *New England Journal of Medicine*, and now occupies one of the highest positions in medical journalism throughout the world.

The first sectarian journal, the *Medical Advocate*, was founded by Samuel Thomson in 1827 to promote the Thomsonian (Botanical) System.

Among the important American medical journals that did not have long lives was the *Transylvania Journal of Medicine and the Associate Sciences* which ran from 1828 to 1839 and included many important papers.

The first American homeopathic journal, the *American Journal of Homoeopathia*, began and ended publication in New York in 1835.

The *Journal of the American Medical Association* began its weekly appearances with Volume 1, Number 1, for July 14, 1883. American medical journals were now being published by a wide variety of commercial concerns, specialty and geographical societies, and by hospitals and medical schools.

The first medical journal to be published in Canada began at Quebec in 1826. The *Journal de Médecine de Quebec* was printed in both French and English although the contents of the two sections were different. This quarterly lasted for two years. The first English-language journal was the *Montreal Medical Gazette* which began in 1845. Medical journalism had spread over most of the country by 1911, when the *Canadian Medical Association Journal* came out with its first issue.

English periodical medical literature was roused out of its quiet existence in 1823 by the appearance of Thomas Wakley's *Lancet*. Wakley believed in responsibility and progress in medical practice, education, and journalism, and the *Lancet* provided an effective platform for his often outspoken comments and aggressive approaches. He backed his beliefs by court appearances as both a plaintiff and a defendant. He even carried his programs into Parliament and was able to lead reform movements in several areas. During his controversial career Wakley kept the level of contributions in the *Lancet* high and it became deeply respected not only in Great Britain but also throughout the world. Of the contributions listed in "Garrison-Morton," 117 were printed in the *Lancet*. The authors included such names as Lister, Simpson, Snow, Horsley, and Fleming.

In 1857 saw the beginning of the other major weekly medical journal in England, the *British Medical Journal*, the official publication of the British Medical Association. The "BMJ" has long maintained a worldwide reputation as an outstanding publication. Lister, Tait, Wells, Osler, and Manson are among the authors who wrote the 122 papers listed in "Garrison-Morton."

The *Edinburgh Medical Journal*, under a variety of titles, had a distinguished career for a century and a half. The *Practitioner* has been making important contributions since 1868 and still holds a respectable position. The *Dublin Journal of Medical and Chemical Science* began publication in 1832 and continues today as the *Irish Journal of Medical Science*.

In 1846 the first issue of the *Australian Medical Journal* appeared, although it ceased publication the following

year. After several other medical journals entered the field the present *Medical Journal of Australia* was formed by an amalgamation in 1914.

The birth and growth of specialty medical journals has been a phenomenon primarily of the nineteenth and twentieth centuries. They have developed at different rates in different countries and their story is too long and detailed for this article. Accounts and pertinent references will be found in the books cited at the end of this entry.

In France the *Archives de Médecine et de Pharmacie Militaires* had a useful career from 1815 to 1882. The *Archives Generales de Médecine* ran from 1823 to 1914, making notable contributions under the editorship of Trousseau. The *Comptes Rendus* of the Academie des Sciences and the Société de Biologie, beginning in 1835 and 1849, respectively, and are still being published. They have carried many important medical papers.

In addition to the journals founded by Müller and Virchow, Germany was the source of many other important titles. *Pflüger's Archiv für die gesamte Physiologie* began publication in 1868; *Langenbeck's Archiv für klinische Chirurgie* in 1861; *Wiener medizinische Wochenschrift* in 1851; *Münchener medizinische Wochenschrift* in 1854 (as *Arztliches Intelligenz-Blatt*); *Berliner klinische Wochenschrift* in 1864; and *Deutsche medizinische Wochenschrift* in 1875. These journals are all still making worthwhile contributions to the literature.

Among the early major Russian medical journals was the *Moskowye Medizhinskaja Gazeta* 1866–1878, the *Wojenao Medizinske Journal* (*Military Medical Journal*) 1823–1907, and the *Wratsch* (*Physician*).

THE TWENTIETH CENTURY

The medical literature of the middle twentieth century has become essentially a journal literature. Articles in journals are now the standard method of announcing discoveries, new methods, and even new hypotheses. Speedy publication, wide circulation, and lower cost have all emphasized the journal over the book. This trend was evident toward the end of the previous century, and could be demonstrated in this century by such items as Joseph Goldberger's first major publication on pellagra in 1920. This was a 109-page report that most probably would have been published as a book earlier, but in the twentieth century it appeared as a journal article.

The book portion of the medical literature showed two major trends in the twentieth century. The first was toward the comprehensive and detailed set, of which the German Handbücher are good representatives. The 12-volume *Handbuch der speziellen pathologischen Anatomie und Histologie*, edited by Henke and Lubarsch and published by Springer at Berlin, 1924–1952, was typical. Another facet of this trend is the multiauthored set, such as Duke-

Elder's *System of Ophthalmology* in 15 volumes. This began in 1958 and Volume 14 appeared in 1972.

The second was a continuation of the trend toward the highly specialized monograph. A classic of this century, Felix d'Herelle's *Le Bacteriophage*, published at Paris in 1921, exemplifies this trend. In the first half of the century this type of monograph could have also been represented by a two-volume one-author work such as Henry Head's *Aphasia and Kindred Disorders of Speech*, published by the Cambridge University Press in 1926. This is still in such demand that a reprint was produced in 1963.

Reference works of several varieties were frequent additions to the medical literature of the twentieth century. These could be works that keep reappearing, such as David Bergey's *Manual of Determinative Bacteriology*, first published at Baltimore in 1923 and now in its eighth edition, or a single-appearance publication such as the World Health Organization's (WHO) *Bibliography of Yaws 1905-62*, printed at Geneva in 1963. The publication program of WHO has made many worthwhile contributions to the medical literature.

Popularizations of scientific medical work for the layman, although not new to the medical literature in this century, have been much more frequent. These serve a variety of valuable purposes.

But essentially this has been the century of the medical journal, and the proliferation and variety of these publications has been remarkable. Journals are now dealing with highly specialized subjects, and the rise and fall of research and clinical fashions can be traced in the corresponding births, mutations, and deaths of the journals.

Whether the journal will remain the chief form of the medical literature for the rest of this century and into the next is an unpredictable matter, although some trends at present suggest that it may not. The printing of separate fascicles of a journal for each separate article has been tried experimentally. Related to this trend is the publication of only an abstract or a tightly shortened version of the article with the storage of the full text in a central location to which readers may write for full copies if they are interested. The medical newspaper is another new phenomenon in the literature.

Medical journals have appeared in microfiche rather than the traditional printed form. So far these have not been too successful, but as a new generation of readers comes along this form of publication may spread.

The audio side of the audiovisual approach has also entered the medical literature. More than a few journals are now available on tape. This is true of the digest type of publication as well as the full-length article variety. The audio method seems to have met with more favorable reader acceptance than the visual.

Books, too, are changing their format. The programmed-learning text with its columns, boxes, and variously sized and shaped pages, is a common sight. The next step is already being taken experimentally, the computerized

nonprinted text. In this case the text of a book (most logically a multiauthored handbook) is stored in a computer and never printed as a whole. When one of the authors wants to bring his section up to date he displays it on the terminal page by page, makes additions, deletions, or corrections, and sends it back to the storage unit. When a reader wants a more permanent copy than the terminal display, he asks for the page(s) he wants to be printed out and sent to him.

The medical literature is now in a state of flux, even more so than it has been in the past. What shapes it will have in 25, 50, and 100 years no one can predict. The only certainty is that it will continue to exist in some form or forms—because both the readers and the authors need it.

BIBLIOGRAPHIC CONTROL

Within 50 years after the invention of printing from movable metal type the medical literature had grown to the point where a bibliography was felt to be needed. Symphorien Champier accordingly compiled his *De Medicinæ Claris Scriptoribus*, which was printed at Lyons in 1506. Champier listed the books in five divisions: ancient medical writers; philosophical medical writers; ecclesiastical writers on medicine; Italian medical writers; and French, German, Spanish, and English medical writers. Dates were infrequently given, and little other information was included beyond author and title. A rough author and subject index was included in the table of contents.

It was 84 years before a bibliographic work showing substantial improvements appeared. (Conrad Gesner never completed the medical volume of his monumental *Bibliotheca Universalis*.) Paschalis Gallus produced his *Bibliotheca Medica* in 1590 at Basel. Again the text was broken down by languages. The bulk of Gallus's text dealt with writers in Latin, and this is a practical annotated list arranged alphabetically by the given name of the author. Gallus's volume was the first general bibliography of medicine arranged by authors with adequate bibliographic information.

The next year Israel Spach published his *Nomenclator Scriptorum Medicorum* at Frankfurt. The text was arranged in a minutely classified format with alphabetical subject and author (given names) indexes. The individual entries contained fairly complete bibliographic information.

Johannes-Antonides der Linden made several substantial improvements in the editions of his *De Scriptis Medicis*. These included practical use of type size and spacing for increased legibility and easier location of information. Although he retained the alphabetical arrangement of authors by given names (really a logical contemporary approach because surnames were not yet widely used), Linden added information to his entries and brought his bibliography close to a modern production. The first edition appeared in 1637 at Amsterdam, and two later ones came out in 1651 and 1662.

In 1686 Linden's work was revised and considerably enlarged by Georg Abraham Mercklin, who took an important step by including for the first time some articles from the periodical publications of the learned societies that were just springing into formation.

In 1679 Martinus Lipenius published his *Bibliotheca Realis Medica* at Frankfurt am Main. He was able to include a large amount of material by using a two-column format in a large quarto volume. Lipenius also used letter headings for each column as a guide to the searcher. The text was arranged by subjects with the authors arranged alphabetically by given name. Many cross references (primarily subject, but some author) were given throughout the text. There was an index for authors, commentators, et al.

Further steps were taken by Cornelius à Beughem who, in 1681 at Amsterdam, published his *Bibliographia Medica et Physica Novissima*. This publication circumvented one of the problems brought on by the increasing outpouring of the medical literature by limiting its coverage to material published within a specific time span, roughly 1651 to 1681. The text was arranged by authors.

In 1696, also at Amsterdam, Beughem produced his *Syllabus Recens Exploratorum in Re Medica*, which covered the periodical literature, mostly from the transactions of various learned societies. In both of these pioneering publications Beughem made improvements in accuracy and detail.

The first "giant" in medical bibliography appeared in the eighteenth century. Albrecht von Haller had compiled a nine-volume work, *Elementa Physiologiae Corporis Humani*, at Lausanne, 1757–1782, in which he listed and annotated many of the publications in that broad field. This was, in a sense, a warm-up for his four major bibliographies. The first of these, *Bibliotheca Botanica*, two volumes printed at Zurich in 1771–1772, contained much medical material. The botanical volumes were quickly followed by the *Bibliotheca Chirurgica*, two volumes, Bern, 1774–1775; the *Bibliotheca Anatomica*, two volumes, Zurich, 1774–1777; and the *Bibliotheca Medicinæ Practicae*, four volumes, Basel, 1776–1788. These were arranged by broad subject, and then chronologically. Many of the items listed had abstracts. There was an author index.

Wilhelm Gottfried Ploucquet initiated the concept of the cyclical bibliography, and his arguments for and against this solution make interesting reading in the introductions to his publications. His first basic set was the *Initia Bibliothecae Medico-Practica et Chirurgica* in eight volumes, printed at Tübingen (as were all his works) in 1793–1796. A four-volume supplement, *Bibliotheca Medico-Practica et Chirurgica*, was printed in 1799–1803. A combined set, with new material, *Literatura Medica Digesta*, appeared in 1808–1809, in four volumes, and one supplemental volume was produced in 1813, the year before Ploucquet's death. Ploucquet was able to put so

much material in the *Literatura* because he used smaller type than previously and a three-column format. All of his works were arranged by subject, and included many journal articles as well as books, pamphlets, and dissertations. Unfortunately, he had no author index.

Between 1830 and 1845 Adolph Carl Peter Callisen produced, at Copenhagen, thirty-three small volumes of his *Medicinisches Schriftsteller Lexicon der jetzt lebenden Aerzte*. . . . This mammoth undertaking provided an author list of books and journal articles printed roughly between 1750 and 1830. This, the last major one-man medical bibliography, made a useful complement to the work of Ploucquet. Callisen's set was reprinted in 1962–1965.

The next outstanding figure was John Shaw Billings who lived from 1838 to 1913. Billings not only realized the bibliographic needs of the users of the medical literature but was able to work out practical publications to meet these needs and workable methods to produce the publications. The first volume of the *Index-Catalogue of the Library of the Surgeon-General's Office* appeared in 1880. The series was to have 60 more volumes before it ceased in 1961. This set (in five series) covered the books and articles in the collection at the Surgeon-General's Library, providing an author and subject approach to the former and a subject approach to the latter. Using typographic aids and a two-column format, Billings was able to make a vast amount of material easily accessible.

The first series of the *Index-Catalogue* included 16 volumes printed between 1880 and 1895; the second series of 21 volumes ran from 1896 to 1916; and the third series of 10 volumes appeared from 1918 to 1932. The fourth series, which went only through "M," was printed in 11 volumes between 1936 and 1955, and the fifth series of three volumes was printed in 1959–1961. The complete set ranks as a major contribution to the bibliographic control of the medical literature, and will serve as a lasting memorial to Billings's imagination, perseverance, and ability. Lack of money and the rapidly increasing flow of the literature eventually made the approach of the *Index-Catalogue* no longer feasible.

Billings envisioned a frequently appearing series as a current supplement to the foundation of the *Index-Catalogue*. The first monthly issues of this supplement, which was called the *Index Medicus*, were printed in 1879. These issues covered primarily articles from selected medical journals although some other material was also included. The text was classified, and the only indexes were the annual author and subject listings. Robert Fletcher assisted Billings with the production of the *Index Medicus* just as he did with the *Index-Catalogue*. A carefully worked-out team handled the processing of the materials and information.

The *Index Medicus* ran into financial difficulties at the end of the century (Ser. I, Vols. 1–21, 1879–1899), and sufficient income was not generated again until the Carnegie Institute helped out and made possible the continuation of this valuable tool (Ser. II, Vols. 1–18, 1903–1920; Ser. III,

Vols. 1–6, 1921–1927). With the third series the *Index Medicus* became a quarterly and took on a subject arrangement with an annual author index.

The American Medical Association produced a similar index with its *Quarterly Cumulative Index to Current Medical Literature* (Vols. 1–12, 1916–1926). The drain on finances and growing production time led to an amalgamation of this with the *Index Medicus* to form the *Quarterly Cumulative Index Medicus* (Vols. 1–60, 1927–1956) which had authors and subjects arranged in an easy-to-use dictionary format. The Surgeon-General's Library (going through an evolutionary series of names) began a *Current List of Medical Literature* during World War II that continued until 1959 and was particularly useful for the period 1952–1959.

With the demise of the *Index-Catalogue* and the *Quarterly Cumulative Index Medicus* a restructuring of the bibliographic mechanism was needed. The coverage of books was taken care of by the Army Medical Library (now the National Library of Medicine) with a sequence of annual and quinquennial catalogs leading up to the *Current Catalog* which began in 1966. Journals were indexed in the “new” *Index Medicus* which began in 1960. This appears in 12 monthly issues and a bound annual cumulation of several volumes.

The mechanization project at the National Library of Medicine that developed along with the new *Index Medicus* under the direction of Frank B. Rogers led eventually to the computerized MEDLARS (*Medical Literature Analysis and Retrieval System*) program, which has speeded up the production of the *Index Medicus* and made computerized searching of the literature a reality, has also led to the development of Medline (the on-line computerized program that provides access to the National Library of Medicine's data banks) and to a variety of related programs. Some of these services have been made available in England, Sweden, and other countries. A greatly enlarged and improved Medlars II program has just been put into operation. An experimental program with the use of a satellite for the communication of medical information has been successfully tried out by the library. The State University of New York has developed a broad computerized program that provides bibliographic control for and access to a vast amount of the medical literature.

Abstract journals have provided another approach to the medical literature. Karl Christian Schmidt initiated *Schmidt's Jahrbücher der in- und ausländischen gesamten Medicin* in 1834. The *Jahrbücher* met such a great need that they continued through 336 volumes until 1922. The Germans developed a network of bibliographic journals based on the Zentralblätter or Berichte in the different

subject areas that provided brief abstracts, through their annual compilations (*Jahresberichte* or *Jahrbücher*) to the review journals usually titled *Ergebnisse*. The major English-language abstracting journal is the *Excerpta Medica* series which began in 1947 and has grown considerably. Indexing or abstracting journals are also found in France, Russia, Japan, and many other countries.

CONCLUSION

The bibliographic control of the medical literature in the Americas has been greatly assisted by such works as the *Epitome de la Biblioteca Oriental i Occidental, Nautica i Geografica* of Antonio de Leon published in Madrid in 1629, the *Historia Bibliografica de la Medicina Española* of Antonio Hernandez Morejon (seven volumes, Madrid, 1842–1845; reprinted in 1965), and the *Biblioteca Hispano-Americana* (1493–1810) of Jose Toribio Medina (six volumes, Santiago de Chile, 1898–1907). Francisco Guerra's *American Medical Bibliography 1639–1783* (New York, 1962), which includes newspapers, broadsides, and almanacs as well as books, pamphlets, and journal articles, is a major bibliographic work, and Robert B. Austin's *Early American Medical Imprints: A Guide to Works Printed in the United States 1668–1820* (1961) is invaluable in its area.

Metadata and Digital Information [ELIS Classic]

Jane Greenberg

Metadata Research Center, School of Information and Library Science, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, U.S.A.

Abstract

The range of metadata activity over this last decade is both extensive and astonishing, and substantiates metadata as an integral part of our digital information infrastructure. This entry begins with a brief history of metadata relating to digital information, followed by an overview of different metadata types, functions, and domain-specific definitions. Next, the family of standards comprising a metadata architecture are defined, followed by an overview of metadata generation processes, applications, and people: this latter section gives particular attention to automatic metadata generation approaches. The following section explores four key metadata models. The conclusion summarizes the entry, highlights a number of significant metadata challenges, and notes efforts underway to address metadata challenges in the new millennium.

INTRODUCTION

Today one can hardly talk about digital libraries, data repositories, and many aspects of the library 2.0/web 2.0 environment without mention of *metadata*. This is because metadata is a crucial part of these digital information systems. Metadata describes information and its context and associations; it is integral to the operation and function of any system preserving and supporting discovery, access, and use of information. Metadata is also a necessary component of physical information systems, such as the traditional library card catalog. In this context, bibliographic records (an equivalent of *descriptive metadata*) represent library holdings and facilitate resource discovery and use.

The first article on “metadata” appearing in the *Encyclopedia of Library and Information Science (ELIS)* was published in 2002,^[1] under the title, “Metadata and the World Wide Web.” This work was revised and republished in 2003.^[2] These noted entries define metadata, compare metadata to library cataloging, describe concepts for discussing metadata, and review different methods for generating metadata.

Metadata developments have matured considerably since these first *ELIS* entries were published, and a number of initially ambiguous aspects surrounding the topic are more fully understood. For example, when the term metadata was first being explored in the library community, via digital library and World Wide Web (web) development, there were efforts to distinguish metadata from library catalog data, including MACHine Readable Cataloging (MARC) bibliographic data. Today, library catalogers and digital library professionals generally agree that MARC bibliographic data is metadata, and that the family of MARC formats—bibliographic, authority control, and

so forth^[3,4]—all have a place within metadata discussions. Another sign of growth is that metadata-related development and inquiry has expanded well beyond National Information Standards Organization (NISO) and the International Standards Organization (ISO) metadata standards to include ontologies,^[5,6] the Semantic Web,^[7] annotation,^[8] and social computing/web 2.0 developments relating to tagging and folksonomy.^[9,10] In short, our perception and comprehension of metadata has been influenced by time and the evolution of technology and information practices requiring metadata.

This encyclopedia entry considers the evolution of metadata and presents a fresh perspective on this topic. The rest of the entry is organized by the following section headers: “Metadata: Origin and History” covers the origin and history of metadata relating to digital information; “Defining Metadata” explains the different types and functions of metadata and presents a series of domain-specific definitions for metadata; “Metadata Standards” defines the family of metadata standards that comprise a metadata architecture—these include data structure standards, content value standards, data communication standards, and syntax standards; “Metadata Generation” reviews metadata generation, processes, applications, people—giving focused attention to automatic approaches; “Metadata Models” explores several key metadata models; and the “Conclusion” summarizes the entry, and highlights several significant metadata challenges being faced in this new millennium.

METADATA: ORIGIN AND HISTORY

The etymology of metadata draws from the classical Greek prefix *meta*, which means “after, behind, or higher;”

and the from Latin word *data*, plural for datum, which means “a piece of information” or “something given.”^[11] Metadata is, in essence, a piece of information generated *after* the object of focus has been produced; and the information given is at a higher level (more abstract) than the object.

Metadata, as an information concept, is known to have first been used in the late 1960s by individuals in the statistics/database community, and it has been recollected that it was a standard word by the 1970s, although references are difficult to find. The first known reference appears in *An Infological Approach to Data Bases*, a doctoral dissertation completed in 1973, by Bo Sundgren, at the Statistiska Centralbyren (pp. 104–105).^[12] This work also includes the concept of *metainformation* and articulates distinctions between the real-world phenomena; information about phenomena; and data representing the information describing the phenomena; the last conception is referred to as meta-metadata in today’s information systems.

The most frequent historical reference given for *metadata* is for a marketing brochure, printed for Jack E. Myers, representing a MetaModel and company products. References credit Meyers with coining the term *metadata* in 1969,^[13] and in 1986 METADATA® was registered as an United States trademark for The Metadata Company (<http://www.metadata.com/>), where Meyers is a principal. Meyers is known to have legally contested the use of term *metadata* by others. However, his ownership claims have been successfully refuted, given the publication of *An Infological Approach to Data Bases* and the longstanding historical use of this term in the statistics community.

Today, the term metadata has been steadfastly integrated into our information culture, and it is generally, although not exclusively, associated with digital information. Evidence of growth includes the increase in people engaged in metadata work in the library and other information intensive environments, such as scientific research centers. As part of this growth we see professional titles like *metadata librarian* and *metadata specialist*. The body of scholarly research on metadata is also expanding; in fact there are two fairly new scholarly journals targeting metadata: *The International Journal of Metadata, Semantics and Ontologies* (<http://www.inderscience.com/ijms>) published by Inderscience Publishers, and *Journal of Library Metadata* (<http://www.tandf.co.uk/journals/>) published by Taylor & Francis. Additionally, the number of books on metadata continues to grow yearly, with very recent notable publications by Riley and Foulonneau,^[14] Zeng and Qin,^[15] and Liu.^[16] Finally, a factor of growth is the Dublin Core Metadata Initiative (DCMI) (<http://www.dublincore.org/>), which has been flourishing since 1995, promoting the Dublin Core Metadata Element Set (DCMES),^[17] an open, interoperable, interdisciplinary metadata standard. The

DCMI and metadata initiatives in the education, science, government, industry, and other communities have been a major force bringing metadata issues to the forefront of library and information science, and demonstrate the wide reach and complexity of this topic.

DEFINING METADATA

Definitions for metadata have been influenced by both the objects to which the metadata is being applied, and the functions it is intended to support. The most often uttered and most inclusive definitions for metadata are *data about data* and *information about information*. Although *data* and *information* can have distinct meanings,^[18] these terms are frequently used interchangeably, and it is not uncommon for metadata to be also defined as *information about data*, or even *data about information*. What makes these definitions high-level is that the “information” or “data” being described connotes an *abstract object*—that is “anything perceivable or conceivable,” as defined in the ISO/IEC (International Organization for Standardization/International Electrotechnical Commission) 11179-1: 2004, Metadata registries (MDR)—Part 1: Framework (p. 4).^[19]

The earlier *ELIS* metadata entries give attention to the unbounded nature of an object as “any *entity, mode or form*” to which metadata can be applied, ranging from “information resources, such as a monograph, newspaper, or photograph—to activities, events, persons, places, structures, transactions, relationships, execution directions, and programmatic applications.”^[1,2] The ways in which people work with and understand information varies enormously across disciplines, cultures, and societal strata, and it follows that their conception of the information object varies as well.

Library and information science is primarily concerned with metadata for *information resources*—the types of *objects* housed in libraries, repositories, museums, archives, and other types of information centers. In this environment, metadata is frequently defined as “structured data about data.”^[20,21] The structured metadata is gathered to form a *metadata surrogate*—a “stand in” for the real resource akin to a bibliographic surrogate.

Metadata surrogates are usually comprised of *descriptive metadata*, which is metadata that supports resource discovery. Detailed, more granular metadata definitions, beyond data about data, emphasize types (or classes) of metadata and the associating functional aspects, such as describing, preserving, and contextualizing information (see Table 1).

Although literature confirms there is no single agreed upon typology of metadata types or functions, metadata discussions promote similar and overlapping labels and definitions (pp. 20–22).^[22] Further, more granular

Table 1 Examples of metadata types, functions and properties

Type of metadata	Function supported	Metadata property (element)
Descriptive metadata	Resource discovery; selection; access	^a Creator; title; subject
Preservation metadata	Resource management	Resolution; density; fixity
Provenance metadata	Lifecycle management; authentication	^a Creator; date created; date modified
Contextual metadata	Awareness; comprehension; interpretation	Date created; temporal data; arrangement (placement of an object in relation to other objects)
Technical metadata	Use; access	System requirements; format
Rights management metadata	Access; reproduction; use/re-use	Rights

^a A metadata property that can be labeled as more than one *type* of metadata is multifunctional.^[22] The Dublin Core property *creator* is identified as “descriptive metadata” because it helps with discovery and “provenance metadata” because it helps with lifecycle tracking; creator is, therefore, a multifunctional property.

definitions are important because they provide insight into the functional aspect of metadata and the way in which different communities work with and understand metadata. The following community-oriented definitions illustrate this point more concretely:

- The *library community* emphasizes *descriptive metadata*; that is “metadata that serves the purposes of discovery (how one finds a resource), identification (how a resource can be distinguished from other, similar resources), and selection (how to determine that a resource fills a particular need, for example, for the DVD version of a video recording)” (pp. 210).^[23,24]
- The *digital geospatial and environmental science communities* have consistently stated that “Metadata or ‘data about data’ describes the content, quality, condition, and other characteristics of data” (p. 1),^[25] providing a definition reflecting needs of associated with digital geospatial and similarly related materials.
- The *business community* highlights metadata for *machine processing* and *user activities*, and adheres to two main metadata classes: *technical metadata* describing database information and machine driven tasks; and *business metadata* supporting input/output tasks overseen by humans (p. 12).^[26]
- The World Wide Web Consortium (W3C) emphasizes the *computing potential* of metadata for growing the Semantic Web, and defines metadata as “machine understandable information for the web” (W3C Metadata and Resource Description: <http://www.w3.org/Metadata/>).

- The social networking and web 2.0 environment promotes the use of the term tag/tags/tagging instead of metadata. Definitions for these terms underscore the functional aspect of tags as “keywords” for *describing, classifying, finding, and sharing* information.^[27]

These more descriptive definitions show a range of activities and functions metadata supports (e.g., retrieval, preservation, and machine processing). The range of definitions also provides insight into the complexity of this topic, and helps explain why, in many respects, the high-level definition of *data about data* is the accepted unifying definition, despite its generality.

METADATA STANDARDS

Metadata generally involves standards. The degree to which standards apply varies tremendously, depending on the object of interest, available technology, and community overseeing the metadata activity. Metadata activities in the library and information community are supported by a series of standards that comprise a metadata architecture. These include: *data structure standards*, *content value standards*, *communication standards*, and *syntax standards*. Although different aspects of these types of standards are generally integrated in a single metadata package, they are reviewed separately here to emphasize specific functions. Many instances of the standards reviewed here are endorsed by agencies, such as the American National Standards Institute (ANSI), National Information Standards Organization (NISO), International Organization for Standardization (ISO), Internet Engineering Task Force (IETF), and the World Wide Web (W3C), and designated by an identifier often consisting of numbers or numbers and letters.

Data Structure Standards

Data structure standards are the most familiar metadata standard. A data structure is essentially a list or container of explicit properties (elements). A data structure standard names and defines the *semantic categories* representing the information system’s metadata. These semantic categories are most often referred to as *metadata elements*, although *metadata facets* are also becoming common. Most recently, the Dublin Core community has been promoting the term *metadata properties* in an effort to align metadata activities with the Semantic Web.

The DCMES, version 1.1 (here after referred to as the Dublin Core) is among the most internationally and interdisciplinary recognized metadata data structure standards. The Dublin Core and is defined as “a vocabulary of 15 properties for use in resource description,”^[17] and is endorsed by the ISO (ISO 15836-2003), ANSI/NISO (ANSI/NISO Z39.85-2007), and the IETF via a request for comment (IETF/RFC 5013-2007). Examples of Dublin

Core properties include *creator*, *title*, and *subject*. An example for the property “creator” from the Dublin Core, 1.1, is provided in Example 1.

Example 1: Characteristics for the Dublin Core Metadata Property *Creator*

Term Name: Creator	
URI:	http://purl.org/dc/elements/1.1/creator
Label:	Creator
Definition:	An entity primarily responsible for making the resource.
Comment:	Examples of a Creator include a person, an organization, or a service. Typically, the name of a Creator should be used to indicate the entity.

Data structure standards are fairly equivalent to data dictionaries developed for databases and frequently include additional information about the use and application of metadata properties. For example, a data structure standard may recommend a *public label*; confirm property *cardinality*—if the metadata property is repeatable; declare property *obligation*—is property required, recommended, or optional; and list legal content values or standards for a property.

Data structure standards have been developed for a wide range of domains. Examples include following:

- *Metadata Object Description Schema* (MODS)^[28] for digital library resources.
- *Visual Resources Association Core Categories* (VRA Core)^[29] for visual resources.
- *Encoded Archival Description* (EAD)^[30] for electronic finding aids.
- *Data Document Initiative* (DDI)^[31] for social science research data.
- *Federal Geographic Data Committee/Content Standard for Digital Geospatial Metadata* (FGDC/CSDGM)^[25] for digital geospatial resources.
- *Ecological Metadata Language* (EML)^[32] for ecological research data.
- *Institute of Electrical and Electronics Engineers/ Learning Object Metadata* (IEEE/LOM)^[33] for digital learning objects.
- *PREservation Metadata: Implementation Strategies* (PREMIS)^[23] for preservation information about any digital object.
- *Darwin Core* (DwC)^[34] for specimen collections and the geographic occurrence of species.

The immediate above list includes only several of the hundreds, and potentially thousands, of metadata schemes that function as data structures. The widespread availability and increased sharing of schemes represents a maturity in metadata development; and it is simply *best practice* to

first consider if a scheme (or schemes) fulfilling project needs has already been developed when embarking on any new initiative requiring metadata. Among incentives for adopting, and potentially modifying, existing metadata schemes are the desire to support interoperability and avoid duplicative efforts. Supporting this trend are *application profiles*,^[35] which are data structures composed of defined properties from established standardized schemes. The DCMI has developed the Singapore Framework^[36] to standardize the creation and documentation for application profiles.

Content Value Standards

Content value standards contain words, names, and symbols connoting meaning. Common types of content value standards include *subject heading lists*, *thesauri*, *classification systems*, *taxonomies*, *ontologies*, and *name authority files* (for people, places, geographical jurisdictions, and other named entities). Content value systems containing concepts used for topical, domain, or intellectual representation are increasingly referred to as knowledge organization systems (KOS).^[37]

Values are drawn from content value standards and paired with properties to complete a metadata record; hence, the common notion of property/value pairs. For example, the Harley–Davidson Web site as a *digital resource* has various properties, such as title, subject, and date. These properties are defined in the Dublin Core, and assigned values to construct a metadata record. Example 2 presents a fragment of a Dublin Core metadata record showing *Library of Congress Subject Headings* (LCSH)^[38] values in XML for the Harley–Davidson Web site.

Example 2: Fragment of a Dublin Core metadata record showing *LCSH* values in XML for the Harley–Davidson Web site

```
<dc:subject xsi:type="dcterms:LCSH" >Harley-Davidson
motorcycle </dc:subject>
<dc:subject xsi:type="dcterms:LCSH" >Harley-Davidson
motorcycle-Collectibles</dc:subject>
```

Content value systems are neither available nor desirable for every property defined in every metadata scheme; and the freedom to create content values via tagging is part of the appeal and success of folksonomies. In fact, one may argue that a folksonomy presents a de facto content value standard via sharing and aggregating agreed upon tags.

Data Communication Standards

Data communication standards are the encoding or markup language that wraps around the property/value pairs in the metadata record. Data communication

standards permit metadata records to be stored, searched, retrieved, and exchanged with other information systems. The prescribed system of punctuation that is part of the International Standard Bibliographic Description (ISBD), and the other ISBD formats that have now been consolidated,^[39] is an example of a pre-Web data communication standard. Developed in the late 1960s, with the eye toward supporting computer exchange of bibliographic data, the prescribed punctuation separates designated areas of description, such as resource “title” and “statement of responsibility.”

Data communication standards commonly used today for encoding metadata include MARC bibliographic format (ISO 2709/ANSI/NISO Z39.2), which incorporates ISBD; eXtensible Hypertext Markup Language (X/HTML; W3C WD-xhtml2-20060726); and XML (W3C REC-xml-20060816). Example 3 presents a MARC bibliographic record with core properties and the XML Dublin Core equivalent for the same metadata.

Example 3: MARC Bibliographic Record and Dublin Core XML Metadata Record for Berners-Lee’s book *Weaving the Semantic Web*

MARC Bibliographic record	Dublin Core XML record
100 1 Berners-Lee, Tim.	<dc:creator>Tim Berners-Lee </dc:creator>

Syntax Standards

Syntax standards are not stand-alone standards designated by an identifier, rather they are integrated each of the standards reviewed, and guide metadata creation and encoding. For example, syntax standardization may dictate element ordering for data structure standards; value structuring for value content standards; and grammar for communication standards. (The word *element* is used in this section instead of property, given that *property* is not as familiar a concept across all metadata communities.)

These aspects of syntax standardization are further explained below:

- *Element ordering*: Data structure standards may include element ordering recommendations or specifications, such as the author/creator element should (or must) always precede the title element. Familiar bibliography standards, such as the American Psychological Association or the Chicago citation style have an element ordering syntax in the way bibliographies citations are constructed; and these standards integrate a grammar syntax (defined below) via prescribed punctuation. There are many data structures, such as the Dublin Core, that do not have a standardize element ordering protocol; however initiatives using such schemes may determine their own standard approach to organizing metadata elements.
- *Value structuring*: Content value standards may include value structuring requirements. For example, *LCSH* has a protocol for constructing subject heading strings [topic—period subdivision]; or [topic—geographical subdivision]. Similarly, the *Art & Architecture Thesaurus*^[40] has a protocol for building faceted strings. The Library of Congress Name Authority Headings (<http://authorities.loc.gov/>) includes syntaxes for named entities following the *Anglo-American Cataloging Rules*.^[41] For example, personal name is structured with the surname, followed by forename (e.g., Picasso, Pablo). There are also syntax standards to help with content values that may not necessarily be taken from a controlled vocabulary. One example is the W3C Date and Time Formats,^[42] a subset of ISO 8601, which recommend the syntax of YYYY-MM-DD for dates and other content syntaxes depending on available date and time information.
- *Grammar syntax*: Communication standards embody a grammar syntax for producing valid encoding. An obvious example is the way in which XML angle brackets are created with a “<” to represent the start of encoding a metadata element, and then use a “/>” to represent closure. Example 3, above, illustrates both MARC and XML encoding syntax. The core of the MARC bibliographic record includes tags (the three digit numbers), delimiters (a dollar sign: \$), and delimiter codes (often lower case letters). The Dublin Core metadata record presents an example of XML grammar, with angle brackets as well as prescribed punctuation.

Standards, as reviewed here, are integral to many aspects of metadata. It is useful to keep in mind that metadata standards are discussed and labeled in many ways, and generally “a said standard” includes multiple aspects or types of standards. A case in point is the *Anglo-American Cataloging Rules*,^[41] which is often labeled as a *content standard*, integrating aspects of a data structure, content

syntax, and encoding syntax (the encoding follows ISBD punctuation). The most important aspect of any standard is that they enable metadata to be used more effectively supporting functions (e.g., resource discovery, management, or authentication); and, at the foundation level, standards guide metadata generation.

METADATA GENERATION

Metadata generation is the act of creating or producing metadata, and can be generated via different processes, applications, and classes of people.^[43]

Metadata Generation Processes

Metadata is generated via manual, automatic, or, a combinatory approach. Manual metadata generation necessitates human engagement (e.g., metadata professionals, content creators, and technical assistants); automatic metadata generation involves the use of machine processing; and the combinatory approach integrates both manual and automatic methods.

An overview of metadata generation processes

It is nearly impossible to find an example of metadata produced entirely by manual means, given that metadata is fairly well rooted in the world of electronic and digital information. In fact, it is commonplace that metadata generation activities include some reliance on technology and programmed algorithms. For example, an application requiring manual metadata input may link to external standards and automatically generate and validate encoding. The OpenSource Metadata Framework (OMF) Template (Example 4) for Linux software and software documentation presents an example, with the last button saying “xmlify.”

Automatic metadata algorithms are frequently in place recording the date the digital object was created or modified, who created the object or its metadata (depending on login information or work station accessed), and size of the object; although, authors and application users are often unaware of these algorithms. The only example of a purely manual metadata approach is the process of *hand-written* labeling, indexing, or cataloging.

Similarly to the near absence of purely automatic metadata generation, most automatic processes require some human involvement to, at the very least, initiate the operation. At minimum the human may need to point the application to a resource identifier as required with DC-dot (<http://www.ukoln.ac.uk/metadata/dcdot/>). Humans are frequently involved in some aspect of metadata evaluation when automatic processes are used, given known shortcomings of machine processing (e.g., limited capabilities to disambiguate among concepts).

Automatic metadata generation approaches

Recognizing that metadata generation generally involves a mix of manual and automatic methods has prompted the metadata community to pin-point areas where human engagement is essential, and where automatic processes should dominate. For example, it does not make sense for a human to manually reproduce resource identifier, such as a URL, when it could be automatically harvested from a Webpage; and the automatic approach is less prone to errors than the manual approach. As part of an effort to advance the development of metadata generation applications, the DCMI Tools Community has prepared a glossary [draft]^[43] defining specific types of automatic metadata generation approaches, which are further articulated here.

- *Derived metadata*: Metadata automatically generated according to system designed (pre-programmed) profiles. For example, a system program may automatically derive metadata values for “date created,” “date modified,” or “resource size.” Profiles can be designed to automatically populate a metadata record with default values, such as “rights access,” or “creator” information.
- *Metadata extraction*: Metadata generated by running automatic indexing algorithm against resource content. For example, term frequency algorithms are used to extract and determine subject keywords; and automatic detection of noun phrases may help extract values for other metadata properties, such as “author,” “date,” and “title.” Semi-structured metadata, determined by the fairly consistent placement of metadata values (e.g., title, keywords, and author names) within document content, can also be extracted.
- *Metadata harvesting*: Metadata is automatically gathered from existing metadata sources, regardless of whether it was originally generated via automatic or manual means. Metadata can be harvested from a range of sources (e.g., a resource header, metadata registries, or database). Metadata harvesting is a key aspect of the Open Archives Initiative (OAI) (<http://www.openarchives.org/>), an electronic pre-print service. Extraction of semi-structured metadata from document content has an element of harvesting.

There are multiple approaches for generating metadata; and the method selected depends on a host of factors. Chief considerations include the type of objects being represented (e.g., online conference proceedings, personal photographs, a scientific data set); the environment where the metadata will be hosted (e.g., a digital library, scientific repository, or personal account on a social networking site); who is creating the metadata; available financial and human resources for the task; and the complexity of and intellectual requirements associated with the underlying schemes and standards used. All of these factors together

have a direct bearing on the type of application selected for generating metadata.

Applications

The range of applications supporting metadata is extensive. The previous *ELIS* entry covered this topic by identifying templates, editors, generators, and document editors. Although these intellectual distinctions are still applicable, these concepts are used interchangeably and inconsistently by application developers and users alike. Another way to view the range of metadata applications available is to consider the context in which they are used, including how they are marketed. Four contexts considered here

include: 1) tools designated specifically as metadata applications; 2) library management systems (LMS); 3) content management systems (CMS); and 4) daily use applications.

- *Metadata applications*: The growing need for metadata has motivated the development of applications specifically labeled as metadata tools. These applications generally provide templates for manual metadata input, and permit manual editing once the metadata is generated. Many of these applications automatically link to property definitions; list acceptable content value standards or even values for selection; and automatically generate XML or other desired encoding, as illustrated with the “xmlify” button in the OMF

Template (Example 4). The Berkeley Web Template CGI script for EAD finding aids (<http://sunsite3.berkeley.edu/ead/tools/template/>), and the hCard Creator (<http://microformats.org/code/hcard/creator>) for hCard Microformats Wiki 2.0 (<http://microformats.org/>) (a standard used to represent people, companies, organizations, and places) are examples of these more manually driven metadata applications.

There are metadata applications supporting a greater degree of automatic processing, such as DC-dot and Metatag Extractor (<http://www.hooverwebdesign.com/tools/metatags.php>). These applications automatically harvest metadata from the resource's source code. Additionally, DC-dot extracts resource content where harvesting proves insufficient and also includes a template for manual editing.

- *Library management systems (LMS)*: As libraries have engaged in metadata generation, library software has integrated the support for metadata standards. Examples include Innovative Interfaces Inc.'s Metadata Builder (http://www.iii.com/products/metadata_builder.shtml), which supports the creation for both Dublin Core and the EAD metadata; and CONTENTdm (<http://www.contentdm.com/>), which supports Dublin Core, VRA Core, and newly created metadata schemes and vocabularies. There are also a number of open source LMS, such as Greenstone Digital Library Software (<http://www.greenstone.org/>), supporting many of the metadata functions found in commercial products.
- *Content management systems (CMS)*: CMS require metadata for content management. Ektron (<http://www.ektron.com/web-content-management-solutions.aspx>) includes basic metadata properties such as title, keywords, language; and this software can be programmed to assign default keywords. IBM Lotus Quickr Web (<http://www.ibm.com/developerworks/lotus/library/quickr-web-services/>) automatically generates date created, last modified timestamps, and identifier metadata to maintain server activities. Similar to LMS, there are many open source CMS that support metadata. Additionally, many CMS integrate taxonomy plug-ins to improve metadata quality. Synaptica® (<http://www.synaptica.com/djcs/synaptica/>) from Dow Jones Client Solutions is among one of the more popular plug-ins for developing and managing taxonomies.
- *Daily use software*: Although this is rather a "catch-all" category, it is the case that anyone working on any type of computer interfaces with some form of metadata generation software, whether or not they are aware of it. Examples include software people use daily to arrange information captured on their iPods, palms, cell phones, and other mobile devices. The AMeGA Report,^[44] produced to address Section 4.2 of the *Library of Congress Bibliographic Control*

Action Plan,^[45] analyzed metadata generation features and functionalities embedded in software people use to create content daily (e.g., Microsoft Word, Adobe, Dreamweaver, and Moveable Type), and found that several metadata elements supported by these applications easily map to the Dublin Core. Finally, and perhaps the most obvious daily use applications supporting metadata generation underlie social networking activities. For example, Flickr (<http://www.flickr.com/>) and Delicious (<http://delicious.com/>) support folksonomic tagging and the generation of metadata, a good portion of which aligns with Dublin Core properties.^[10]

Classes of Persons

Among the classes of persons involved in metadata generation, are professional metadata creators, technical metadata creators, content creators, and public metadata creators.

- *Professional metadata creators* include catalogers, indexers, and other individuals who have had formal education or official on-the-job training to learn about metadata standards and issues; and they generally work in libraries, archives, publishing houses, and formal information agencies. This class of persons is known as third-party metadata creators because they produce metadata for content created by other individuals. Professional metadata creators have the intellectual capacity to make sophisticated interpretative metadata-related decisions, work with classificatory systems and other complex content value systems, and have some theoretical understanding of metadata. Given expert knowledge, the professional's greatest contribution may be evaluating metadata, managing metadata generation activities, or helping to develop tools that facilitate effective and expedient metadata production.
- *Technical metadata creators* include data in-putters, paraprofessionals, and other individuals who generally have had basic training, but have not participated in a formal structured or certified educational program. Technical metadata creators are also third-party metadata creators, and generally not assigned the same degree of responsibility as a metadata professional; however, they may take on more sophisticated tasks over the duration of their work-life.
- *Content creators* are individuals creating metadata for intellectual content they have authored. There are many types of content creators—authors of text, photographers, creators of video—amateurs, professionals, and the average citizen.

Authors of scientific publications regularly engaged in metadata generation in the pre-Web environment by writing abstracts, identifying keywords, and even assigning

classificatory indicators when submitting their work via peer-review channels. The online peer-review process has maintained these author metadata requirements. An example is the Association of Computing Machinery/Special Interest Group (ACM/SIG) Proceedings Templates (<http://www.acm.org/sigs/publications/proceedings-templates>), which require authors to select “categories and subject descriptors” from the *ACM Computing Classification Scheme*.^[46]

The content creator metadata environment is thriving today via developments such as the OAI, institutional and specialized repositories (e.g., GenBank, <http://www.ncbi.nlm.nih.gov/Genbank/>, for gene sequences), and social networking sites, where people create metadata to share photographs (e.g., Flickr), bookmarks (e.g., Delicious), news (e.g., Blogs), and news about oneself (e.g., Facebook, <http://www.facebook.com/>).

- *Public metadata creators* include community or subject enthusiasts who create metadata for a resource authored by other individuals. A subcategory of public metadata creators includes *users*—people creating metadata by annotating content they have used, and sharing their insights.

During the very early years of the Web, 1995–1999, people created lists of hyperlinks for topics they were passionate about (e.g., travel, sports, cooking, pets, politics, and entertainment), resulting in personal subject gateways. These personal undertaking included basic metadata: title, creator, and sometimes an annotation. While these types of Web sites are still visible, public metadata creators have generally turned to social networking sites to share favorite Web sites, tag information, blog, or annotate information.

Public metadata creators help build collective knowledge through their efforts, and are increasingly being accommodated in reputable information systems. For example, WorldCat (<http://www.worldcat.org/>), a service connecting more than 10,000 libraries worldwide, has introduced a user tagging option. This service allows users to manage bibliographic records and enhance resource discovery for other WorldCat users. The Steve project (<http://www.steve.museum/>), a partnership between leading museums and the general public, is another important example exploring how social tagging can enhance access to museum collections and further engage visitors.^[47]

Professional catalogers and metadata experts are not able to handle the sheer volume of information being generated today; and it is not feasible to ask these highly skilled and paid individuals to create metadata for every digital object, particularly when there are other individuals and applications to help with the process. It is, therefore, encouraging to see the increased functionalities in metadata application and more and more people engaging in metadata generation.

METADATA MODELS

The increase in metadata generation has encouraged the development of metadata models supporting interoperability, data reuse, and more intelligent packaging of metadata. This section reviews four key models gaining acceptance in the metadata community, although there are many additional models.

Arguably the most simplistic model impacting metadata developments is the Resource Description Framework (RDF).^[48] RDF is a simple model for rendering metadata instances into simple discrete and explicit statements (Example 5). The overriding goals of RDF are to impose structure, facilitate the unambiguous and consistent expression of semantics, and support more intelligent use of Web data. RDF underlies the Web Ontology Language Overview^[49] and Simple Knowledge Organization System^[50]—two key specifications for developing the Semantic Web.

RDF statements are frequently referred to as *literals* or *triples*, and include a subject, predicate, and object (Example 5); these statements can be visually represented via RDF graphs (Fig. 1).

Multiple RDF statements can be made about the same object. Additionally, RDF supports an iterative process, whereby an “object” of one RDF statement could be the subject of another RDF statement. A statement illustrating iteration might say that the “subject” *Harley-Davidson motorcycle* (from *LCSH*) (which is the “object” in Figure 1), has a “predicate” *identifier* (the LC control number) with the “object” (meaning the *value*) 85058931 (see Fig. 2).

RDF was initiated as a model that does not necessarily need to be expressed in XML. However, RDF implementation is supported by series of additional specifications addressing the syntax, vocabulary, and semantics for creating RDF/XML statements that permit metadata to be shared. Conceivably, once an RDF statement is made about an object on the Web, that statement (a metadata

Example 5: RDF triple

Subject	Predicate	Object
The subject (meaning the resource) http://www.harley-davidson.com	Has a predicate (a Dublin Core property) The “dc.subject”	Containing object (a value; and in this case an <i>LCSH</i> value) “Harley-Davidson motorcycle”

Fig. 1 RDF graphical representation for the triple in Example 5.

instance) can be reused again and again, although more development is needed to truly share and reuse RDF renderings.

Another model increasingly being discussed in the metadata community is the Functional Requirement for Bibliographic Records (FRBR),^[51] published by the International Federation of Library Associations and Institutions. A body of research has advanced knowledge about the bibliographic object and the notion of the *work*^[52,53] in our online library catalogs. Building on these advancements, the FRBR model includes four entities: *work*, *expression*, *manifestation*, and *item*. The partitioning of bibliographic data (or metadata) following FRBR allows for data reuse; more sophisticated linking of entities; and a richer descriptive environment. The model is still heavily conceptual, although there are instances of FRBR implementations, most notably OCLC's Fiction Finder (<http://fictionfinder.oclc.org/>).

FRBR's foundation work predates the Web; and, yet, it is extremely applicable to the digital world, where resources are copied and modified rapidly, and the reuse of bibliographic data is an important goal. FRBR presents library users with an opportunity for gaining a greater understanding of the bibliographic universe from where they gather sources; and, in the long run, FRBR could prove extremely cost effective, not only for users making important links among resources, but by eliminating duplicative metadata efforts. These goals have inspired additional FRBR efforts relating to name and subject authority data.

The Metadata Encoding and Transmission Standard (METS)^[54] is another model being used in the digital library/repository environment. METS is a framework for packaging descriptive, administrative, and structural metadata within an XML framework, and wrapping that metadata around a digital resource. As digital initiatives began to proliferate toward the end of the 1990s, the need for different types of metadata standards supporting

different functions became increasingly evident. This need led to interest in developing a consistent way to package resource metadata drawing from different standards—a goal that was further motivated by the need to enable greater interoperability and reuse of the resource and its associated metadata. The Making of America-2 (MOA-2) (<http://sunsite.berkeley.edu/moa2/>), a Digital Library Federation project, formalized these ideas and created a XML/document type definition (DTD) for packaging metadata; and these efforts progressed to form what is today METS.

METS has the following seven key sections: 1) *METS header* for describing the object; 2) *descriptive metadata* linking to external metadata (e.g., a MARC bibliographic record or a Dublin Core record, representing the object, but stored elsewhere), and internal descriptive metadata enriching external descriptions; 3) *administrative metadata* documenting creation, source, and rights information both externally and internally; 4) *file section* listing all files comprising the digital object; 5) *structural map* outlining the resource's arrangement and linking to the object's content; 6) *structural links* recording hyperlinks between sections of an object's content; and 7) *behavior* documenting and pointing to executable behaviors associated with the METS object's content, or code for initiating an operation.

The Dublin Core Abstract Model (DCAM)^[55] is among the more recent metadata models. The DCAM incorporates RDF and has been developed to advance the metadata development, and to bring metadata activities more in-line with the Semantic Web initiative. Two key principles underlying DCAM are: 1) a resource can be any type of discrete entity (as discussed above in "Defining Metadata" section), and 2) metadata can be created for any object. The DCAM asserts that a metadata record can include one or more metadata statements; and a simple RDF statement is an acceptable metadata record. This approach differs from traditional notions of a bibliographic cataloging, where a metadata record includes multiple property/value pairs. The DCAM is "object centered," and the emphasis is on cataloging objects (e.g., words, numbers, discrete entities) at the most discrete level, so that the object and metadata are reusable. The majority of metadata work is resource centric—with resource referring to an entire Web site, or the types of entities collected by libraries, albeit digital (e.g., books, reports, photographs). Implementing metadata within the

Fig. 2 RDF graphical representation for the "subject" *Harley-Davidson motorcycle* (an LCSH heading).

DCAM requires a new, more object-centered perspective for metadata. DCAM is in its infancy, but the approach may transform metadata activities to a new level.

CONCLUSION

Metadata is a dynamic topic and has evolved considerably since the initial *ELIS* metadata entry was published in 2002.^[1] This current entry stands as a new article, with fresh coverage of the earlier topics (e.g., the definition of metadata and metadata generation), and greater attention to metadata models. This entry provides new facts uncovered on the history of metadata; presents an overview of different metadata types, functions, and schemes; provides a series of domain-specific definitions for metadata; and discusses the various types of standards comprising metadata architectures.

The remarkable growth in metadata activities has been extremely positive, resulting in greater access to information and better documentation. However, like many developments, this growth has not been without challenges. Determining how to generate metadata (emphasizing an automatic or manual approach), and who to involve in the process (professionals, technical assistants, content creators, the public), presents metadata quality and workflow challenges. Striving for interoperability and sharing metadata can pit local metadata needs against higher level goals. And, perhaps the most exciting challenges stem from the goal of *metadata reuse*. Those engaged in metadata activities debate if metadata should be generated for every discrete object and if a more globally linked Semantic Web is achievable. Efforts underway, such as the Dublin Core Singapore Framework^[12] guiding application profile development, and the National Science Digital Library Metadata Registry (<http://metadataregistry.org/>), for sharing metadata schemes, provide a means for addressing several metadata reuse challenges. These efforts will, no doubt, continue to evolve through evaluation and use. And, as metadata progresses, new challenges will undoubtedly surface, and new solutions will be sought.

It is clear that metadata is an ubiquitous topic and an integral part of our digital information infrastructure. Education, the arts, science, industry, government, and the many humanistic, scientific, and social pursuits that comprise our world have rallied to develop, implement, and adhere to some form of metadata practice. There is ample evidence showing that metadata has touched nearly every discipline and societal sector coming into contact with digital information. The goals are similar across the board—to facilitate the preservation, discovery, access, and sharing of digital output. In closing, the range of metadata activities over this last decade are both extensive and astonishing, and presents an unprecedented

opportunity to share information and knowledge as we move forward in this millennium.

Metam Markup Languages: SGML and XML

Airi Salminen

Department of Computer Science and Information Systems, University of Jyväskylä, Jyväskylä, Finland

Abstract

Current global communication of people and software applications over the Internet is facilitated by the use of markup languages. This entry introduces the principles and different types of markup, and the history behind the current markup languages. The basis of most of the modern markup languages is the Standard Generalized Markup Language (SGML) or its restricted form Extensible Markup Language (XML). Both of them are metalanguages that are used to define specific markup languages for specific application areas. The entry describes the markup techniques used in SGML and XML, gives examples of their use, and briefly describes some representative SGML and XML applications from different domains. An important factor in the success of XML has been the possibility to reuse markup vocabularies and combine vocabularies originating from different sources. The entry describes the concepts and methods facilitating the reuse of names from earlier defined vocabularies.

INTRODUCTION

Markup languages have become an important means to communicate information on the Internet. On November 2014, Google search markup language derived more than 29 million hits, mentioning on the first pages, for example, the following languages:

- Standard Generalized Markup Language (SGML)
- Extensible Markup Language (XML)
- HyperText Markup Language (HTML)
- Emotion Markup Language
- Chemical Markup Language
- Graffiti Markup Language
- Music Markup Language
- Geography Markup Language
- Systems Biology Markup Language
- Theological Markup Language
- Election Markup Language
- Fountain: A markup language for screenwriting

The list clearly shows the diversity of application areas where markup languages have been developed. This diversity is an important reason for the fact that not only information specialists but also many application domain specialists face the need to understand the principles of markup languages. The first two on the list, Standard Generalized Markup Language and Extensible Markup Language, better known by their acronyms SGML and XML, respectively, are not languages for a particular application domain but *metalanguages* that are used as a basis to develop markup languages for various domains. From the languages of the list Emotion Markup Language, Chemical Markup Language, Graffiti Markup Language, Music

Markup Language, Geography Markup Language, Systems Biology Markup Language, Theological Markup Language, and Election Markup Language are XML-based languages. HyperText Markup Language instead, also known as HTML, is a markup language older than XML and based on SGML, the “mother language” of XML. The last in the list of languages represents markup languages that are not based on SGML or XML.

The markup techniques in the contemporary markup languages are intended primarily for computers. Markup as a technique to add information to documents is, however, older than computers and originally intended for human use only. This entry first introduces different types of markup and provides a classification of the types. A brief history of SGML^[1] is then provided, examples of the most important SGML applications are given, and reasons for the evolution of XML^[2] from SGML are described. The markup in SGML and XML is intended to indicate two different structures in documents: a logical structure and a physical structure. The markup techniques to indicate those structures in documents are described and some examples are given. Neither SGML nor XML provides a predefined markup vocabulary, instead they include a definition capability to describe markup vocabularies for particular application areas. The vocabularies carry semantic information to the human users of the languages. The definition mechanism is introduced briefly, the topic is covered more extensively in another entry of the Encyclopedia. XML-based languages have been developed for various domains. This sectoral development has been facilitated not only by XML but also by the XML family of languages developed at the World Wide Web Consortium (W3C), the organization coordinating web technology development. At the end of the entry, a

classification of the XML family of languages is introduced and some representative languages are briefly described.

MARKUP TYPES

Markup can be divided into different types based on its function. Fig. 1 describes a taxonomy of markup types. At the highest level, markup is divided into two categories: markup intended for human use and markup intended for computer use. Each of these categories is further divided into subcategories. The principles of the markup types, shown in Fig. 1, are described in the following text.

Markup for Human Use

Markup has been the traditional editing technique used in text publishing. Copy editors have added special marks as instructions *for typesetting* a manuscript to be printed. This kind of markup can be called *presentational* because it is intended to inform the typist about the intended external presentation of the text.

The term “markup” is in some sources used also to cover those notations in documents that are intended *for human reading* to make the text understandable. This type of markup has been divided into *punctuational* and *presentational*.^[3] As an example, consider a situation where I want to communicate to my friend Mary Lynn, a proposal to meet her the same day at the statute by Henry Moore in front of the Toronto City Hall, known by Torontonians as The Archer. Text written in haste either by hand on a piece of paper, or by a mobile phone, might first look something like this:

```
April22HiMaryLynnLetusmeettoday4pmatThe
ArcherAiri
```

By punctuational markup I can make this text more readable:

```
April 22 Hi MaryLynn! Let us meet today
4 pm at The Archer. Airi
```

Punctuational markup includes spaces, commas, and other punctuation marks facilitating the separation of words and other syntactic units in text. In addition to the punctuational markup, I might want to use presentational markup to make the text still clearer to read:

```
April 22
```

```
Hi MaryLynn!
```

```
Let us meet today 4 pm at The Archer.
Airi
```

Here the presentational markup includes an empty line, beginning of text from a new line, and indentation. In a longer text presentational markup might include page and list numberings, underlinings, and so on.

Markup for Computer Use

The markup intended for computers has to be formal and systematic. The term “markup language” refers to a language with formal syntactic rules for markup. The markup can be regarded as metadata adding some information to some primary data, often intended for human perception. The early markup languages were developed for text processing systems to instruct software the way the content should be formatted. For example, in a UNIX operating system environment the message to Mary Lynn might have been written in the following way:

```
April 22
.sp 1
Hi Mary Lynn!
.in 5
Let us meet today 4 pm at The Archer.
Airi
```

Here the markup consists of the formatting commands informing the *nroff* text editor how to print the text. The

Fig. 1 Taxonomy of markup types.

first nroff command on the second line instructs the text processor to leave one line of blank space and the second command on the fourth line instructs the processor to indent the following text by five white spaces. Also the space in the beginning of the last line represents markup, because in nroff, a line beginning with spaces is an instruction to begin the text on a new line. This kind of markup for a computer software is called *procedural*. Procedural markup is tied to a particular function in software processing, like in the earlier example where .sp 1 is tied to the line skipping function.

Procedural markup can be used for different types of processing instructions, and accordingly divided into subtypes. The procedural markup intended for formatting is *presentational*. Other subtypes of the procedural markup are referential and metamarkup.^[3] *Referential* markup is used to inform the processor to replace a reference by some value. For example, in some Scandinavian text the strings ä and ö might be intended to be replaced by the text processor by the letters ä and ö, respectively. *Metamarkup* includes notations for defining markup rules for a particular application area. The definitions in XML represent metamarkup and some of them will be considered later in the entry.

The formatting instructions given by means of procedural markup as earlier are embedded into the content of the document; changing the formatting requires changing the document. For two kinds of formatting, two documents with the same primary content have to be written. An alternative to the procedural markup is *descriptive* markup describing the structural components of the document without specifying the processing to be performed on them. Different software applications can then process the structure in their own ways. For the purposes of printing or displaying, the format can be attached as a separate *stylesheet* document.

Fig. 2 shows the previous message written by means of descriptive markup. The markup consists of tags of the form <...> and </...>. The tags indicate the beginning and end of the structural components in the message and give also names to the components. A structural component starts by a tag of the form <...> and ends with </...>. The markup does not refer to the external presentation of the message.

Even though procedural and descriptive markup can be seen as alternative types of markup, it is, however, not rare that a particular markup serves both purposes at the same time. The HTML mentioned in the beginning of the article and familiar to many readers is an example of a language where descriptive markup is used to describe the structure of the external presentation of a document. In such a case, descriptive markup is also presentational.

The principle of descriptive markup has been an important facilitator in the evolution of the current information networks where people, organizations, and computers are connected to each other globally. The widespread

Fig. 2 An example of descriptive markup.

adoption of the principle was initiated with the open standard called SGML.^[1]

BRIEF HISTORY OF SGML

The problems related to the automated text processing of documents with embedded formatting instructions were identified in the 1960s. As early as 1967 in a meeting of the Canadian Government Printing Office, William Tunnicliffe pointed out the importance of the separation of information content of documents from their format and called for “generic coding” of documents instead of “specific coding”.^[4] The idea of generic document coding was an important feature in the language Charles Goldfarb, Ed Mosher, and Ray Lorie invented in 1969 at IBM. The ideas of the language were published in the 33rd annual meeting of the American Society for Information Science in 1970.^[5] The language was first called Text Description Language. In his article in the ACM SIGPLAN/SIGOA conference in 1981, Goldfarb adopted the term *Generalized Markup Language* (GML, nicely referring also to Goldfarb-Mosher-Lorie) for the language developed at IBM and the term “descriptive markup” to the document coding style in GML.^[6] In the same article, Goldfarb emphasized the importance of rigorous markup: the markup should be rigorous facilitating systematic, automated processing of sets of documents of certain types.

The principle of descriptive markup evolved at the time when programming language community started pointing out the difference between procedural and non-procedural programming. In the non-procedural programming, the idea was to give a prescription for solving a problem without showing *how* it is solved.^[7] Similarly, descriptive

markup is intended to describe the structure of a document without indicating *how* the parts of the structure should be processed. Different processing functions can be attached to the structure, either in the software or in separate specifications. The principle of descriptive markup was implemented in the SCRIBE system even before the implementation of GML.^[8] The first implementations served well as a proof-of-concept, but for broader adoption of the principle it was important to find an agreement of standardized rules for descriptive markup. The work toward such rules started in a committee of the International Organization of Standardization (ISO). The first chair person of the committee was Charles Tunncliffe and the concrete development work was done primarily by Charles Goldfarb. The work resulted in *Standard Generalized Markup Language* (SGML), accepted as an ISO standard 8879 in 1986.^[11] The markup in Fig. 2 is an example of SGML markup. To support rigorous markup SGML included the capability to define markup languages by means of *Document Type Definitions* (DTDs). Thus SGML could be used as a *metalanguage* to define special markup languages for special needs as *SGML applications*.

SGML APPLICATIONS

In the 1980s, the definition capabilities of SGML were used, in particular, to define special markup languages for publishing industry, technical documentation, and electronic humanistic texts. Table 1 shows some important SGML applications.

DocBook was developed by private companies especially for authoring and publishing books and articles.^[9] Currently, the DocBook schema is maintained by OASIS (Organization for the Advancement of Structured Information Standards, <http://www.oasis-open.org/>). The development of markup languages for technical documentation was activated strongly by the US Department of Defense under the Continuous Acquisition and Life-Cycle Support (CALS) initiative.^[10] The purpose was to support the weapon system acquisition and life-cycle management. The markup needs of electronic humanistic texts differed from the needs of book publishing and technical documentation. A consortium called Text Encoding Initiative (TEI) was established in 1987 to develop and maintain methods for encoding humanistic texts in electronic

form. SGML-based TEI guidelines were published in 1994, including, for example, markup vocabulary for prose, verse, drama, and dictionaries.^[11]

The most popular SGML-based markup language was born in 1991, when Tim Berners-Lee and Robert Cailliau designed the World Wide Web (WWW) at European Organization for Nuclear Research (CERN).^[12] The language was called HyperText Markup Language (HTML),^[13] and it was used in the new innovative application to present hypertext documents interlinked to each other on the Internet. In HTML, the SGML-based declarative markup also serves as procedural markup to instruct the web browser in the document presentation and in opening new web pages.

The adoption of WWW expanded rapidly in the beginning of the 1990s. New kinds of businesses evolved, based on the connectivity of people all over the world and connectivity of software applications. A great deal of new business ideas were tested on the web, only a few of them were, however, commercially successful. Drawbacks in the business did not prevent the expansive growth of the Internet. At the end of the century, the number of computers connected to the Internet exceeded a hundred millions.

FROM SGML TO XML

The amount of information resources on the Internet started quickly expanding after the invention of WWW. A rich variety of people and software applications were connected to each other through WWW and had, at least in principle, access to huge information resources with textual and multimedia content. The communication of the applications was, however, often hindered by the differences in the representation of data. This was a great barrier for effective use of the Internet, particularly for business purposes. It became urgent to find some common rules for representing information and information structures within Internet and for exchanging information between applications over the Internet. SGML basically offered such rules, but the rules of SGML were too complicated for the needs of the Internet. One of the problems of SGML was the difficulty of building software supporting SGML in general, not only a particular SGML application like HTML. The development of a restricted form of SGML for the purposes of the Internet

Table 1 Some SGML applications.

SGML application	Main purpose	Developing organization
DocBook ^[9]	Book and article publishing	First private companies, later OASIS
CALS DTDs ^[10]	Technical documentation, life-cycle management of weapon systems	US Department of Defense
TEI ^[11]	Electronic encoding of humanistic texts	TEI Consortium
HTML ^[13]	Publishing hypertext documents on the WWW	European Organization for Nuclear Research (CERN)

communication started in the mid-1990s by a group of people. A goal was to simplify the language so that the design and implementation of software for it would not be too tedious. The W3C established in 1994 took responsibility for the development work and published the first version of the restricted form of SGML by the name Extensible Markup Language (XML) 1.0 in 1998.^[12]

Compared to SGML, the number of rules in XML is clearly smaller, and its character set and resource identification mechanisms are planned for use on the Internet. Text in XML documents is encoded for computers using the Unicode character set. Unicode is intended to serve as a character set for representing textual data for computers written in any natural language of the world, independently, for example, of the writing direction of the language. The markup concepts and the DTD mechanism of XML are inherited from SGML. The descriptive markup in Fig. 2 is an example of XML markup as well as of SGML markup. A great deal of the SGML applications are currently also available as XML applications. For example, the markup recommendations of the TEI are available also for XML encoding. For web publishing, there is the Extensible HyperText Markup Language (XHTML)^[14] that facilitates the use of HTML tags by following the rules of XML. For the latest HTML version called HTML5, XHTML syntax has been defined along with the HTML syntax.^[15]

MARKUP TECHNIQUES OF XML

The XML is intended to support computerized use, exchange, and processing of information in documents, especially on the Internet. A goal in the XML development has been to keep it as stable as possible. During the years, some needs for changes have, however, evolved and therefore a new version XML 1.1 was published in 2004.^[16]

The XML specification of W3C describes the markup rules for XML documents and also partially the behavior of a software module capable to deal with the features common to all XML documents. The module is called an *XML processor*. It is used to read XML documents and check that they follow the rules defined in the

specification. In case a DTD is attached to the document instance, the XML processor may also check that the markup follows the constraints in the DTD. XML processor thus performs the parsing of the document. Therefore, an XML processor is often called also an *XML parser* or an *XML validator*.

The XML processor is not an independent piece of software but a module working for a software application. After the parsing the structural components are forwarded to the application. For example, web browsers like Internet Explorer and Mozilla include an XML processor as a component. By opening a file with the filename extension .xml, the XML processor of the browsers checks that the file follows the markup rules of XML and informs about possible errors. Both of the browsers show the file in a pretty-printed form as shown in Fig. 3.

Figs. 2 and 3 showed an example of marking up the logical structure of an XML document. Besides the logical structure, an XML document has a physical structure. The two structures and the corresponding markup are described as follows. At the end of the section, a concise introduction to the DTD capability of XML is provided.

Logical Structure

Even though the markup vocabularies of different XML-based languages differ from each other, there are some common rules all *well-formed* documents have to follow. The logical structure of every XML document is a hierarchy of *elements* indicated by explicit markup. The beginning of an element is shown by a *start-tag* of the form `< ... >` and the end by an *end-tag* of the form `</ ... >`. Both tags include the *name* of the element. Element names provide a capability to add semantic information to the structural markup. The text in Fig. 2 is an example of a well-formed XML document. The element names in the markup of the example were chosen such that they tell something about the meaning of the elements to a human reader. The outermost element is called *message* and the element has three *child elements*: *begin*, *main_content*, and *end*. The element called *message* is the *parent element* of the three child elements and also the *root element* of the document. The element

```
- <message>
  - <begin>
    <date>April 22</date>
    <salute>Hi Mary Lynn!</salute>
  </begin>
  <main_content>Let us meet today 4 pm at The Archer. </main_content>
  - <end>
    <salute>Cheers,</salute>
    <signature>Airi</signature>
  </end>
</message>
```

Fig. 3 The pretty-printed format of the markup text of Fig. 2 in Mozilla browser.

Fig. 4 Graphical representation of the tree structure of the example in Fig. 2.

begin is the parent of two child elements: date and salute. The element end is the parent of two child elements: salute and sender. Graphically, the logical structure of the document is shown in Fig. 4. In the pretty-printed form of web browsers (as shown Fig. 3), the hierarchic structure is utilized by allowing the user to unzoom or zoom branches in the tree structure. The minus character preceding the begin-tag indicates that the element has child elements and the child elements are presented on the screen. By clicking the character -, the child elements will be hidden and the minus character will be replaced by the plus character +.

The text between the start-tag and the end-tag of an element is called the *content* of the element. All elements having the same name in a document belong to the same *element type*.

The markup consisting of tags adds to the text the hierarchic structure and gives names to the structural components. A further means to add information to elements is the use of *attribute specifications*. An attribute specification can be added to the start-tag of an element, after the element name. For example, one might use an attribute to indicate that the content of the element main_content is English:

```
<main_content xml:lang="en">Let us meet
today 4 pm at The Archer.</main_content>
```

Since the capability of presenting content with various natural languages has been found important in XML, a predefined attribute `xml:lang` has been defined to identify the language in which the content of an element is written. The prefix `xml` indicates that the name `xml:lang` is a reserved name from the XML specification. The values of the attribute have to be given by the codes defined by the Internet Engineering Task Force (IETF).^[17] In the example, the attribute specification indicates that the content of the element is in English. The example shows that there are two different techniques for providing a piece of data in XML elements: as element contents and as attribute values.

Physical Structure

Each XML document has actually, in addition to the logical structure, also a physical structure. Also the physical structure has to be indicated by markup. The physical structure of an XML document consists of units called *entities*. Each document has a special text entity called *document entity* or *root entity*. All entities referred to directly or indirectly from the root entity are regarded as parts of the physical structure of the document. The entity mechanism can be utilized to include non-textual data in a document. Thus in its physical structure an XML document may be a multimedia document having along with textual parts other forms of data, for example, audio or video data. For example, we might add to the message of Fig. 2 a reference to the photo of the sender by means of the attribute photo.

```
<sender photo="airi-image">Airi
</sender>
```

The attribute value "airi-image" is the name given to the entity elsewhere in the document.

Another type of an entity is a named piece of text introduced in an *entity declaration*. In other parts of the document, an *entity reference* is then used to refer to the text piece, in the same way as macros are used in many programming languages. For example, by giving the name W3C to the text piece

```
"World Wide Web Consortium"
```

we can refer to the text by the entity reference `&W3C;`. The symbol `&` starts the entity reference and the semicolon ends it. In processing the document, the XML processor replaces the reference by its value before transmitting data to the application. All entity references in XML documents represent procedural referential markup, not declarative markup. Entities provide an important means to include non-textual data to documents and to support consistency and reuse of the textual content.

Document Type Definitions

The previous sections described what kind of markup is used to indicate the logical and physical structure of a document. Extensible Markup Language also provides metamarkup capabilities to define markup languages for specific domains by means of DTDs. A DTD defines the grammar for the documents of a type. Fig. 5 shows a DTD for a message. The first line shows that the document type is called message and the last line closes the definition. The DTD describes the element types used in the documents of the type message, their names, and the way the documents are structured from elements. Altogether, eight element types are defined. Each of the lines beginning by the word ELEMENT is a grammar rule defining the structure of an element type. The name of the element type is given after

```

<!DOCTYPE message [
<!ELEMENT      message      (begin, main_content, end)>
<!ELEMENT      begin        (place?, date, salute)>
<!ELEMENT      place        (#PCDATA)>
<!ELEMENT      date         (#PCDATA)>
<!ELEMENT      salute       (#PCDATA)>
<!ELEMENT      main_content  (#PCDATA)>
<!ELEMENT      end          (salute, sender*)>
<!ELEMENT      sender       (#PCDATA)>
]>

```

Fig. 5 A Document Type Definition.

the word `ELEMENT` and the structure of the elements is given between parenthesis after the element type name.

The first element type definition in Fig. 5 defines the root element `message`. A message is defined to consist of three elements: `begin`, `main_content`, and `end`. The `begin` element always contains a `date` and `salute`, in the beginning possibly a child element called `place`. The optionality is indicated by the question mark. The notation `#PCDATA` is used to indicate that an element consists of character data, without having any child elements. The element called `end` first has a `salute` and then possibly `sender` elements. The repetition of zero or more times is indicated by the symbol `*`. Fig. 2 showed a message following the constraints defined in the DTD. It is called a *valid document* of the type `message` because it is well-formed and follows the rules expressed in the DTD.

COMBINING MARKUP LANGUAGES

A significant factor in the success of XML has been the idea that the work done in an environment for developing markup vocabularies and software can be reused in another environment without being forced to reinvent well-understood concepts and structures. Combining markup vocabularies from two different environments has required solving two problems: identification problem and name collision problem.

Identification Problem

If concepts defined in an environment are intended to be reused and shared in other contexts, there is a need for the unique identification of the original definitions.

Name Collision Problem

When earlier defined names are adopted from two different contexts, it is possible that the same name is used with different meanings.

These two problems have been solved by means of the *XML namespace* mechanism.^[18] A namespace consists of a set of names having a unique identifier. The names may be

defined, for example, in a DTD, but no constraints have been set to the way the names are described and defined. For the unique identifier instead, there are formal syntax rules, the identifier has to be given by using the syntax of the Uniform Resource Identifier (URI).^[19] The most common form of a URI reference is the Uniform Resource Locator (URL) used in the WWW to refer to resources available on the Internet. For example, the URL `http://www.w3.org/` is the address of the main page of the W3C site. A URI reference can also be a Uniform Resource Name (URN) intended for persistent identification of resources to remain the same even when the resource becomes unavailable. As namespace identifiers, URIs are always considered as identifiers of abstract resources. The definitions of the names may be available on a particular Internet site, but the namespace identifier is not regarded as the address of the site even though the format would be that of the URL. For example, if people at the University of Jyväskylä agree of a set of names and “`http://jyu.fi/names/`” as its identifier, the identifier can be used whether there is something on the web address or not.

In case of namespaces intended for widespread use, the developing organizations may provide some information on the address of the namespace identifier. For example, the W3C has published the URI “`http://www.w3.org/1999/xhtml`” as the identifier for the element and attribute names in the XHTML language and on the page at `http://www.w3.org/1999/xhtml` some information about the specifications where the XHTML names are defined.

As mentioned earlier, reusing names requires solving parallel with the identification problem also the name collision problem. In XML documents the name collision of element and attribute names is avoided by means of qualified names. A qualified name consists of two parts: a namespace name as a prefix and a local part. The namespace name is identified in the document by a URI reference, but the name used as the prefix can be chosen locally. Fig. 6 shows an example how a message could be markedup using TEI element names. Instead of choosing own element names like in Fig. 2, the TEI standardization work is utilized. The name `tei` used locally for the TEI namespace is introduced by the namespace declaration:

```

<message xmlns:tei = "http://www.tei-c.org/ns/1.0">
<tei:opener>
<tei:date>April 22</tei:date>
<tei:salute>Hi Mary Lynn!</tei:salute>
</tei:opener>
<main_content>
Let us meet today 4 pm at The Archer.
</main_content>
<tei:closer>
<tei:salute>Cheers,</tei:salute>
<tei:signature>Airi</tei:signature>
</tei:closer>
</message>

```

Fig. 6 A document using names from the TEI namespace.

```

<message xmlns:tei = "http://www.tei-c.
org/ns/1.0">

```

The name is associated with the URI identifying the TEI namespace. The element names *opener*, *date*, *salute*, *closer*, and *signature* are taken from the TEI namespace.

XML FAMILY OF LANGUAGES

The simplicity of XML has encouraged active development work around XML, including both software development and development of XML applications and related languages. Where SGML has been primarily in use as a format for documents intended for human readers, for example, in the form of HTML documents, the use of XML has extended toward data interchange between software applications.^[20] Development of XML-based markup languages has been going on in various standards development organizations. For example, the OASIS (<http://www.oasis-open.org/>) has coordinated the standardization for health care and business needs.

Probably the most important standards developing organization is the W3C (<http://www.w3.org/>). The organization was founded in 1994 to coordinate and support international, open development of technologies related to the web. W3C publishes technical reports called *W3C Recommendations*, which are considered to define web standards. The Recommendations and their preliminary versions are published at <http://www.w3.org/TR/>. During the first 16 years of XML, W3C has developed a family of languages and published Recommendations for over 50 XML-related languages. The intent has been to specify syntactic and semantic rules either for some specific kind of XML data or for data to be used together with XML data for a specific purpose. A web portal maintained by the

author of the entry since the year 2000 provides a classification of the languages, and it shows for each language its standardization phase, related specifications, and links to the W3C technical specifications.^[21] The classification is introduced and some of the languages in each class are briefly described as follows.

Four main categories on the basis of their purpose have been identified in the XML family. The first category consists of the different versions of XML itself. The other three categories are called XML accessories, XML transducers, and XML applications:^[20,21]

XML accessories are languages that are intended for wide use to extend the capabilities specified in XML. An example of XML accessories is the *XML Schema* language extending the definition capabilities of XML DTDs. XML Schema allows the use of a variety of data types, for example, boolean, float, int, date, and their validation in conforming software. In addition to a number of built-in data types, the schema designers may define user-derived data types. XML Schema definitions can be written using XML syntax, but other presentations are possible, too. When using XML syntax, the schema is an XML document that can be processed by general XML software.

XML transducers are languages that are intended for transducing some input XML data into some output form. Examples of XML transducers are the style sheet languages Cascading Style Sheets (CSS) and Extensible Stylesheet Language (XSL) intended to produce an external presentation from some XML data, XSL Transformations (XSLT) for transforming XML documents into other XML documents, and XML Query Language (XQuery) for querying collections of XML data both locally and on the web, be it physically stored in XML or viewed as XML via middleware. A transducer language is associated with some kind of processing model that defines the way output is derived from input. From the four example languages, CSS does not have XML syntax while the rest of the languages have.

XML applications are languages that define constraints for a class of XML data for some special application area. As mentioned earlier, XML accessories and XML transducers are often XML-based languages and thus also XML applications. The languages in the XML applications category can be further divided into four subcategories according to the application area:

Non-textual forms of data: The character data of markedup XML are usually shown to the human reader as text. Non-textual data like graphics or voice are attached to the document as external entities. There are, however, also markup languages available to present non-textual data by means of markedup text. In the XML family of W3C such

languages are, for example, Synchronized Multimedia Integration Language (SMIL) for multimedia documents, Scalable Vector Graphics (SVG) for vector graphics, and Voice Extensible Markup Language (VoiceXML) to enable access to the web using spoken interaction.

Web publishing: The languages in this group are intended to replace the SGML-based HTML gradually by XML-based representation formats. The most important language in this group is *XHTML*, reformulation of HTML in XML. The latest version of HTML, called *HTML5*, has been defined with two syntaxes: one in HTML and the other in XHTML. Extensible Hypertext Markup Language is a content language aimed at many kinds of devices in addition to laptops and workstations, including TV screens of various sizes, hand-held computers, and portable phones. Therefore, there are several variants of the XHTML markup and also a possibility to embed other markup within XHTML to facilitate displaying non-textual markedup data by browsers. Current browsers already support the use of markup beyond XHTML. For example, Google Chrome, Safari, and Firefox browsers allow combining XHTML and SVG markup.

Semantic Web: To facilitate more effective use of resources on the web, W3C has started to develop rules for adding semantic metadata to the web. Important languages developed for the purpose are Resource Description Framework (RDF) to describe resources, RDF Vocabulary Description Language (RDF Schema) to define RDF vocabularies, and Web Ontology Language (OWL) for publishing and sharing ontologies.

Web communication and services: There is a great need to facilitate secure exchange of data and services between software agents of the Internet. W3C has developed a number of markup languages for the purpose. For example, *XML-Signature* defines syntax and processing rules for XML digital signatures. It is intended to provide integrity, message authentication, and signer authentication services for data. Simple Object Access Protocol (SOAP) is a lightweight XML-based protocol for exchange of information in a decentralized, distributed environment. Web Services Description Language (WSDL) can be used to define web service interfaces and functionalities so that services needed for a particular situation can be automatically accessed and chained with other services.

CONCLUSION

The interconnectivity of people, computers, software agents, organizations, and services on the web is enabled

by hundreds of different markup languages, either based on SGML or its restricted form XML. The web users do not necessarily have any need to be aware of the markup. Understanding the principles of markup techniques and markup languages is, however, essential to all information specialists. Also for application domain experts involved in the development of markup languages for the particular domain, it is important to be aware of the possibilities and constraints of markup techniques.

Why XML has been so widely adopted? Some kind of markup is always needed in digital documents to enable automated processing of documents. Compared to other kinds of markup techniques XML provides several benefits. Some of the important benefits are summarized here. First, like SGML, XML is a metalanguage enabling definition of special vocabularies and document structures for various application domains. Rigorous markup using specified vocabularies facilitates automated processing of documents of certain types. For example, it is possible to develop information retrieval tools where the queries are expressed using the terminology of the particular domain. Second, SGML and XML are open standards supporting long-term accessibility of information in data assets of organizations. Information in SGML and XML documents is not accessible by a particular software application only, but by diverse software. And if necessary, the markup is readable also to human individuals. Third, compared to SGML, XML is simpler and provides stronger support for programming. Thus, it has encouraged the development of a great number of software for processing XML data. Last, SGML was developed to be used as a document format, for example, for technical documents and publication industry. XML can be used for the same purposes but also, and is probably used more, as a format for data exchange between software applications. This feature supports interoperability of software applications.

The entry first introduced and classified different types of markup emphasizing the importance of the invention of descriptive markup. Three major milestones in the development of the markup languages were described. First, the development and standardization of the rules for descriptive markup in SGML. Second, the birth of the most important SGML application called HTML for the language of the WWW. Last, the development of XML to support more effective communication on the Internet. An overview of the markup techniques and definition capabilities in XML was given. XML-related development work has been a huge collaborative effort in many standards developing organizations. The sectoral standardization has benefited substantially from the development work of the W3C that has resulted in not only XML but also the namespace mechanism to facilitate combining and reuse of markup vocabularies and over 50 other XML-related standards. The XML family of languages was introduced, and some representatives of the languages were briefly described.

Mexico: Libraries, Archives, and Museums

Jesús Lau

Library Services Unit USBI Veracruz (USBI VER), University of Veracruz, Veracruz, Mexico

Abstract

This entry offers a general introduction to the different types of Mexican libraries, museums, and archives, with an emphasis on libraries and related subjects such as serials, book production, and library schools. Literature was consulted and direct data was gathered from Web sites and through telephone interviews of knowledgeable library professionals. Data used in this entry is not all recent. Therefore, it is used mainly as an indicator of the general status of Mexican information development.

GENERAL BACKGROUND

Mexico is a large country, whose official name is Mexican United States, a federal constitutional republic. It is politically divided into 31 states and a Federal District (Mexico City). Its government is presidential with a constitutionally strong Congress and a supreme court. The president is elected for a non-renewable 6-year term and appoints the cabinet. The country's legislature is based on a bicameral Congress: 128-member Senate, and a 500-member Chamber of Deputies, elected for a 3-year term.^[1] States provide some funding for education and libraries, as well as setting some of the educational requirements, but policy-making is generally centralized by the federal government. For example, the Ministry of Public Education provides funding and direction, in different levels, to all types of libraries, except special ones. Mexico, as a country, has more than 100 million inhabitants; it is certainly the most populated nation in the Spanish-speaking world. Covering a territory a quarter of the size of the United States of America (U.S.), its economy ranks number 14, according to its Gross National Income, and it ranks number 7 in terms of tourism.^[2,3] Mexico is the second largest economy in Latin America. It is a country in an intermediate advanced stage of development with a positive economic performance that is closely linked to the American economy. The official concern in dealing with poverty persists and the per capita income has gone up, although poverty and inequality rates continue to be elevated.^[2] Libraries are a crucial service to enhance information development of the country, whether at schools or in the workplace. Therefore they are assumed to be a means to bridge the socio-economic gaps in Mexican society. This entry provides a general description of the libraries, providing a historical introduction, a brief account by type of library, and a description of related subjects, such as book and serial publishing, among other library and information subjects. Museums and archives are also included as repositories

for the collection and preservation of culture whose roles complement that of the libraries. The general goal is to give the international reader a general picture of the range of library institutions, stressing their contemporary developments.

HISTORY

Locations for the reproduction, transmission, and promotion of information existed in Mexico well before the Spaniards arrived in 1519. The Aztecs had library-like institutions called Amoxcalli, the house of the Amoxtli, the pictographic codices that recorded economic, social, and political life in this central Mexican Kingdom. This was also the case of other indigenous cultures with urban centers, such as the Maya. Some of the existing codices are preserved, mainly in European institutions, since few Amoxtli works escaped the burning and destruction of the Spanish missionaries in their quest to convert locals to the Catholic Church. The most famous existing codex is the Borgia. It originally included five parts^[4] that are now scattered in different European libraries and museums. Libraries in the sense of the western world developed in Mexico after the Spanish Conquest. The first Spanish settlers founded some of the earliest libraries in temples and seminaries, where collections had basically religious books. One of the first books brought to the American continent was a breviary *Libros de Horas* by Jerónimo de Aguilar, the interpreter of the leading conqueror Hernán Cortés. Cortés's party was shipwrecked but managed to save the book in 1511.^[4] It is estimated that two decades later there were more books in Mexico because by 1534, the cathedral had officially a library and its own printing press. The first printing press was brought to Mexico from Seville by Jacobo Cromberg, along with the printer Juan Pablos, in 1539. It also became the first printing press in all of the Americas. An early newspaper was published

that consisted of loose sheets with news of New Spain and was distributed at the beginning of the sixteenth century by Sigüenza y Góngora. The first book to be printed, on the other hand, a religious book, was the *Brief and more compendious Christian doctrine...* (Breve y más compendiosa doctrina Cristiana...) by Zumárraga that is now lost but is recorded in the *Acts of Indias* (Actas de Indias) in the General Archive of Indias in Seville, Spain. These two works made Mexico the first country to publish in the Americas.^[5]

The key political position of colonial Mexico, as the crown colony of New Spain, offered the opportunity to import recently edited books from Spain by transatlantic Spanish travelers. Mexico, for example, was one, if not the first, to receive a copy of *Don Quixote* by Miguel de Cervantes, the equivalent of Shakespeare in the Spanish-speaking world. Members of religious groups played an important role in creating libraries, such as Eguiara y Eguren, a religious scholar and author of the first national bibliography on the continent (1755). These groups founded libraries primarily in Mexico and also in colonial America. The colonial libraries were basically for Spaniards and not for Indians or *Mestizos* (inter-racial people with one Spanish and one Indian parent), who were deprived of education or any formal school training. This library/educational discrimination began to change after Mexico's independence (1810) movement^[5] when public institutions were decreed to be for the entire population. Mexico was in turmoil during the first half of nineteenth century, with constants revolts and conflicts with European countries and the United States, resulting in the United States gaining more than half of Mexico's territory. Other than the creation of the National Library (1867) and the legal deposit (1812), this was a period of minor library development. Later, when the Republic was consolidated during the Porfirio Díaz regime (1876–1910), libraries were officially open to anyone, but illiteracy was high—only 10% of the population could read. This limited access to written culture continued up to the Mexican Revolution, 1910–1919. After this long internal conflict, libraries began to evolve, and had some initial success with the Vasconcelos public library program that started in 1921,^[6] discussed in the public libraries' section of this entry. The decades from 1920 to 1960 were a formational period, with some additional basic library institutions being created, such as the first library school and the library association. The significant library development that occurred after 1970 is described in the following sections of the entry (see Appendix 1).

ACADEMIC LIBRARIES

Mexico has, basically, four types of academic libraries: state university libraries, technological institution libraries, teacher's institutions libraries, and private university

libraries. The first three groups, as may be expected, are financed by government, either federal or state, and seldom by municipalities (counties). The total number of universities varies according to the consulted source. The National Association of Universities and Higher Education Institutions, or ANUIES (Asociación Nacional de Universidades e Instituciones de Educación Superior) that includes mainly state universities, and some technological institutes and a few private ones, reports 127 public and 263 private higher education institutions.^[7] However, the total for all types of institutions, small and large, is 1482 according to statistics from the National Institute of Statistics and Geography, or INEGI (Instituto Nacional de Estadística y Geografía).^[8,9]

State University Libraries

This first group includes the best academic libraries. They belong to the 45 state higher education institutions that are normally the largest in every state and in the Federal District, i.e., Mexico City.^[7] There is one state university per state, except in seven, where there are two higher education institutions, and Mexico City, which has several.^[7] All of them are autonomous: they can take their own academic and organizational decisions, unlike other higher education institutions in the other categories. State universities provide undergraduate education to 2,528,664, i.e., 36.9%^[7,8] of the national student population. Libraries in these institutions are affiliated under the National Council for Library Matters of Higher Education Institutions, or CONPAB (Consejo Nacional para Asuntos Bibliotecarios de Instituciones de Educación Superior) that includes, as full members, 41 members and 8 guest academic libraries whose parent organizations cannot be fully defined as universities.^[10] The academic libraries of Mexico City, such as the Autonomous National University of Mexico, or UNAM (Universidad Nacional Autónoma de México) and the Metropolitan University, or UAM (Universidad Metropolitana) are not included, apparently because of their overpoweringly large size and overwhelming influence. Most state universities have a library system that includes a main library, and one per faculty or cluster of faculties or research centers with a director general. This is reflected in the large number of CONPAB libraries, with 713 units. Few universities have fully centralized services. Those that do are newer, i.e., founded after the 1970s. Generally, CONPAB libraries have centralized acquisitions, collection development, and technical services. The larger academic libraries usually belong to the older and larger universities, such as UNAM, regarded as a special case because of its enormous size (see Fig. 1). It is the oldest university in Mexico and one of the oldest in continental America with nearly one-third of a million students, 299,723. Slightly more than half are undergraduate, 167,891; one-third is high school, 107,482; and the rest are postgraduate students.^[11] The research output is strikingly higher than any

Fig. 1 UNAM Central Library, Mexico City—by Adolfo Rodríguez.

other institution in the country, with 35% of the scientific output, as measured by the number of refereed journal articles. This academic performance makes UNAM number 150 among the 200 best research universities, according to the British newspaper *The Times Higher Education Supplement* assessment of 2008.^[12] UNAM's research activities are dependent on a good library and information service. Including special libraries, UNAM has 142 libraries, with over six million volumes and has the largest library budget for serials, monographs, and electronic resources in the nation. This amount is probably the equivalent of 50% of the total national budget of academic libraries in Mexico. After the National University, the two other large universities are the Universidad de Guadalajara with 195,116 students and 162 libraries,^[13] and the Universidad Autónoma de Nuevo León, with an enrollment of 126,000 students and 80 libraries,^[14] both located in the two other major cities. Their library systems are also well-funded and well-organized. The rest of the state universities have, in general, large library collections, and hold—like the metropolitan universities of the three major cities—important rare, special, and historical collections; they usually have more professional librarians than other type of libraries.

Besides their own institutional budgets, state university libraries are generally financed through the Integral Program for Institutional Support, or PIFI (Programa Integral de Fortalecimiento Institucional), in addition to their own institutional budgets.^[15] PIFI is managed by the General Directorate of Higher Education under the Ministry of Public Education, or SEP (Secretaría de Educación Pública), which uses the funds to set university policies and determine priorities for state-financed higher education. It provides funds on competitive bases to different academic functions, but it has a special fund for academic libraries. Since its inception under a different name in

1980, PIFI has played a decisive role in increasing library collections; acquiring electronic resources, computer equipment, and information technology; training personnel; and furnishing libraries. The challenge that libraries have with these funds is that there is an annual competition for their projects and the money may or may not be awarded, making funding erratic. Librarians do not know if they can count on the funds for the following year. Some changes have been planned to make tri-annual allocations, but, so far, these have not been fully implemented. State university libraries that have been able to attract the most funds, either from PIFI, or from their parent organizations, are UNAM (most successful), and those from the universities in the states of Colima, Jalisco, Ciudad Juárez, Veracruz, Quintana Roo and the Yucatán. In addition there are about 20 other State University library systems whose organization, funding and services are very good. The best accredited universities, included in the previous figures, are grouped in the Mexican Consortium of Universities, or CUMex (Consortio de Universidades Mexicanas), a body created by SEP, that includes 17 institutions. The library systems of CUMex members generally match the academic excellence of the universities in which they are found, and receive some special funding as a reward for their accreditation achievements (see Fig. 2).

Technological Institute Libraries

Technological institutes total 242, the first having been founded in 1949, plus the large National Polytechnic, or IPN (Instituto Politécnico Nacional),^[16] located in Mexico City. IPN is to technological institutes as UNAM is to universities; it was the first and is the largest technological higher education organization in Mexico with 142,861 students. It has 72 libraries, including specialized ones that

Fig. 2 Universidad Veracruzana Library, Boca del Rio, Veracruz—by Ulises Buendía.

serve faculties and research centers in its different campuses. IPN library and information services are larger and better than those of any other technological institution in Mexico, but certainly of a smaller library size when compared against those of UNAM, its State University Library counterpart. Technological institutes, on the other hand, as their name implies, cater mainly to science and technology disciplines, basically engineering, and, to a lesser extent, to management subjects. Technological institutes, originally modeled on the IPN structure, but in an independent network, are run by a centralized directorate in Mexico City under the umbrella of the Ministry of Public Education that provides all the funding and generates library policies at the national level. The network includes engineering, marine, forestry, and agricultural institutes. Their libraries, or information centers, as they are called, have similar information services, including the same type of buildings across the country. Their library development is fairly good, but their budgets are low and their information technology lags behind that of the state university libraries.

There are, in addition, two types of technological universities: technological and polytechnic. Both are newcomers on the Mexican education scene. The first technological universities were founded in 1991.^[17] Each of them receives joint funding from the state where it is located and from the federal government. Degrees are of the 2-year college level, called “Técnico Superior Universitario.” The current number 65 centrally coordinated from their headquarters in Mexico City. Their total enrollment was 66,660 students nation-wide in 2006,^[18] and several had fewer than a thousand learners. The academic structure is a hybrid because they aim to provide, at least by name, technological training with university-based education to support the productive and service

sectors. In most states, they are located in cities with no traditional universities—only 30% are in state capitals. The polytechnic universities, on the other hand, are an even newer development within the national education system. They were created to compliment the technological universities, so that college students could pursue higher education following 2 years of college. To date, they number 22 and their funding is awarded in similar proportion by federal and state governments. Libraries at these universities are in the process of basic development with small spaces, usually a classroom-type accommodation, limited budgets and few professional staff. However, there are some exceptions, such as the polytechnic university libraries of Santa Catarina in Nuevo León and in Aguascalientes, with excellent facilities.

Teachers’ Institution Libraries

There are 457 teacher’s Institutions, usually called *Normales*.^[19] In addition, pedagogical and education studies are offered at state and private universities, but their library resources are included under the corresponding type of institution. There are four types—the oldest date from the 1800s. The first one was founded in 1823, and a handful more was created in the following decades, but the rest was founded in the twentieth century. They are in most state capital cities and tend to be well-established. The second type or generation of pedagogical *Normales* is from the previous century, when several were founded outside the state capitals, and even in the rural areas. The third type is the higher education *Normales*, whose studies are equivalent to undergraduate degrees. The fourth group is comprised of a fairly new network of 76 state pedagogical universities (Universidades Pedagógicas) with 206 sub-sites in major urban centers. The universities were

started in 1978 when the National Pedagogical University, or UPN (Universidad Pedagógica Nacional) the primary leading institution, was created in Mexico City. Library services at the generally older teachers training institutions range from good to fairly good, while second-generation *Normales* and pedagogical university libraries have poorer development, with smaller collections and less organization. The state UPN's libraries are normally housed in classroom-like facilities with basic information services, except the one in Mexico City that has good library premises and good services.^[20] The Pedagogical University sub-sites do not have libraries as such, except for some minor book collections. Teacher's Institution Libraries do not, in general, subscribe to electronic information sources, nor have access to information technology, except for computer and Internet access. In addition, there are more pedagogical and education studies at state and private universities, but they are included under their corresponding type of institutions.

Private University Libraries

Private university libraries vary dramatically according to the size of their parent institutions. According to the Ministry of Public Education, there are 667 institutions of this type. There are a handful of large private universities, over 100 medium-sized, private universities; and over 500 small ones.^[21] The large private institutions are, in general, excellent. Their libraries are well-funded and provide excellent information services. An example is the Technological Institute of Higher Education Studies in Monterrey, or ITESM (Instituto Tecnológico de Estudios Superiores de Monterrey). ITESM is the largest private university with a national network of 33 campuses, each with a library. The largest are in Monterrey, Mexico City, and Guadalajara. Other large private universities with excellent libraries include Anahuac with 10 campuses, University of Monterrey (Universidad de Monterrey), Ibero-American University (Universidad Iberoamericana) with 5 campuses outside the national capital, plus other universities with outstanding library services, such as University of the Americas (Universidad de las Americas, Puebla), Valle de México, Technological Autonomous Institute of Mexico (Instituto Tecnológico Autónomo de México), and Panamerican, among others. The private institutions in the second tier are mid-sized. They are normally affiliated with the Federation of Private Mexican Institutions of Higher Education, or FIMPES (Federación de Instituciones Mexicanas Particulares de Educación Superior),^[22] a national association that includes 114 institutions. That is about 17% of the private universities, according to the FIMPES Web site. The rest of the private institutions range from the common one-school centered program to the more than two-faculty larger programs. These smaller and newer private universities struggle to have and maintain library services. Their collections and

services tend to be minimal and the institutions seldom hire a librarian for their libraries. The Ministry of Public Education regulates their creation and their awarding of university degrees but fails to regulate minimum library standards. The focus of the small institutions, as it is also true for the majority of private universities, is teaching. The faculty members at the small institutions seldom do research, so libraries are not a priority.

In total, academic institutions comprise 1482 libraries, out of the more than 2000 estimated learning centers of all types. State university and large private universities provide the largest library budgets, the fastest growing information collections, and offer the most innovative provision of services. They are also the main customers of international vendors, the leaders in acquisition of technological equipment, and the libraries with the best Internet infrastructure among all types of academic libraries.

PUBLIC LIBRARIES

After the Mexican Revolution of 1910–1919, Jose Vasconcelos, the first minister of public education (1921–1924), created a nation-wide public library program. His dream was to take books to every town in Mexico, and his administration created around 2500 libraries with small holdings that included classic works of literature and technical books.^[23] Following his service as minister of public education, he became the first director of the central public library, Biblioteca Mexico, in Mexico City. Many of Vasconcelos' public libraries unfortunately disappeared, in part due to the limited education system and the high illiteracy rate in the country. Five decades later, public libraries entered their second golden period, from the late 1970s up to the present. A strong well-financed federal government strategy to organize public libraries began in 1978, under Guadalupe Carrión, as public libraries' director. In addition to a national plan to develop a library system, the first 5 years focused on reorganizing libraries at a national level, including a study conducted to assess public libraries, and developing indicators and parameters for building, equipping, and creating library collections, as well as completion of a national plan to develop a library system. Additionally, a major achievement was the training of about 500 public library staff members, with a well-organized and intensive full-time 3-month library program offered in three regional centers in the country: Durango, Mérida, and Querétaro.

In 1983, based on the seminal planning work of the previous 5 years, the National Program of Public Libraries was officially announced by the current President and the Minister of Public Education in turn, who appointed Ana María Magaloni as director general. Under the auspices of this program, a strong national public network was created in the next 5 years.^[24] The department became the General

Fig. 3 Municipal Public Library, Tlaltetela, Veracruz—by Edna Zamora.

Directorate of Public Libraries, or DGB (Dirección General de Bibliotecas), currently managed by the National Council for Culture and the Arts, or CONACULTA (Consejo Nacional para la Cultura y las Artes) of the Ministry of Public Education. The Directorate finances and manages 7211 public libraries with 36.5 million books. The library system is the largest in Latin America, even larger than that of Brazil, whose population is double that of Mexico. The network has a central public catalog for all holdings of public libraries in the country, using the Dewey Decimal System and the Anglo-American Cataloging Rules. The library staff of the public library network includes 10,485 people, whose library training is, unfortunately rather limited. Only 43 have library technical training, 111 have undergraduate degrees, and only two have master's degrees in library science.^[5] However, the general directorate has had library professionals on its staff since its inception in 1978. Perhaps, this fact has been crucial to achieving the current success of the public library network.

Public libraries are grouped into three types: state, regional, and municipal libraries. Their size and services are closely related to their network status. There is a public library in every town with more than 5000 inhabitants. Libraries also vary in size and services from those in the urban centers, which are better equipped, to those in rural towns and villages, where Internet access is almost nonexistent (see Figs. [3–5]).

Public libraries are set up by a joint agreement among the three government tiers. The federal government central office, in Mexico City, is in charge of creating library policies, collection development, acquisitions and technical services. State governments pay for the construction or adaptation of buildings, and the municipal/county

authorities, in turn, hire staff and pay for staff salaries. The program has been successful, especially in those states where their governments invest more in the library network, such as is the case in Veracruz and Chiapas. All 31 states and the Federal District have a central public library that is generally large and well-equipped, with good information services. In most cases, these libraries are in charge of the state public library networks, house the state directors, and provide centralized technical services.

Providing Internet access in public libraries has been a major task for most governments at all levels. In 2002, the Bill and Melinda Gates Foundation donated 30 million dollars to Mexican public libraries. The funds were to equip 1500 public libraries with 1–10 computers, train personnel, and introduce the Internet. This grant was the second given outside the United States, after Chile, by the Bill and Melinda Gates Foundation. The Mexican federal government matched the gift with 40 million dollars. Additionally, more libraries were equipped with computers and Internet access with more federal and state funds, and now 38% of the libraries have computers. Some states provide extra funds to promote Internet access, such as the State of Veracruz, with the recent launch of an ambitious program to provide computers to public libraries and to build regional central public libraries, whose constructions showcase modern architecture. The Bill and Melinda Gates Foundation gave their annual 2008 Access to Learning Award to Veracruz for its innovative efforts to connect people from rural and remote communities with the services provided by 20 all-terrain buses converted into mobile-classroom units. They provide information services, free access to computers, and satellite Internet. Veracruz also provides free access to

Fig. 4 Municipal Public Library, Tlacotalpan, Veracruz—by Edna Zamora.

some commercial information databases in their public libraries. The state of Chiapas does this as well, and offers the additional benefit of making the databases open to any remote user within its geographical limits.

The federal CONACULTA Directorate of Libraries is housed in the large, beautiful, seventeenth century historic premises of the Ciudadela, along with the Biblioteca Mexico main public library, as it was originally called, later renamed Biblioteca Vasconcelos. It hosts public library network services and a collection of 250,000 volumes and will soon have additional new premises. A new state-of-the-art building will soon re-open (it opened for a few months, then closed for further construction) at the former Buenavista railroad station in Mexico City.^[25] The

building, more than 475,000 sq. ft, has a striking modern architectural design, with glass, steel, and concrete playing key roles to create a building that will either be adored or despised, depending on people's artistic perception. A special feature is a botanical garden that gives a natural touch to the building. The design was the result of an international contest with over 592 architects' proposals from all over the world.^[25] The library has an auditorium, meeting places, a bookstore, cafeteria, and plenty of room for stacks and services. It is certainly the largest public library in Mexico and in Latin America. User demand is expected to be high, because it is conveniently located next to the new suburban train station, designed to serve most citizens living North of Mexico City.

Fig. 5 Municipal Public Library, Monterrey, Nuevo León.

The Universidad de Guadalajara in the western part of the country has also broken ground on a larger public state library. Since 1861, the University has managed the state public library Juan Jose Arreola. It holds a rich collection of 400,000 historical books and documents. The current building in downtown Guadalajara dates from 1959. However, the collections have outgrown the facility and the new library (43,000 m²/462,848 sq. ft) will have room for more collections and newer services. The library will be the central unit of a large grand cultural complex that will also include convention facilities. It is planned to open in 2010.

SCHOOL LIBRARIES

School library policies are generally managed by the Sub-Ministry of Basic Education (Subsecretaría de Educación Básica)^[26] of the Federal Ministry of Public Education, its 31 state counterparts, and the Federal District. Most, if not all pre-elementary, elementary, junior high, and high schools, have some sort of book collections, even those in remote rural schools. The books may be in a bookcase or in wooden or cardboard boxes, or whatever container is available in the less well-equipped institutions.^[25] The Ministry of Public Education has created different programs in the past to provide complementary reading materials to schools. Two of the latest are *The books of the corner* (Los Libros del Rincón), a program that provided between 150 and 300 titles of selected literary materials to every school over 4 years beginning in 1986.^[27] This program was superseded by another one that started in 2002, as part of a general reading plan called *Towards a country of readers* (Hacia un país de lectores) that included the *Classroom library* (Biblioteca de aula) program. Its aim is to stock every kindergarten and elementary school classroom with books at the beginning of each school term. In the last 5 years, a staggering figure of over 200 million volumes was given to libraries and classroom collections, making almost nine volumes available to each school child, for the 23 million pupils who attend school. The book stocks include about 50% literary works, and the rest of the books provide general information to support school teaching programs. The titles distributed varied from 218 provided to pre-elementary schools (that received a total of 57 million volumes) to 514 titles provided to elementary schools (that received 78 million volumes), and 488 titles given to junior high schools, who, in turn (that got almost 30 million volumes). These figures also include 51 bilingual titles in Spanish and local indigenous languages.

The book stocks were selected with the participation of teacher focus groups from most states. The program also includes a library training program with a manual on how to organize library materials, how to create library activities and promote reading, plus a set of posters, flyers, and

television and radio programs. The teaching staff who runs the program number more than 6000, and include some who work in libraries.^[28] As a general comment, book budgets are seldom available for libraries or schools themselves. Material acquisition is centralized in SEP headquarters. Public libraries, on the other hand, support schools' information demand with their open role as community information centers, where buildings and services are more broadly and better structured. Public libraries, in general, tailor their information services to better serve students rather than the average citizen, defining themselves as places for those studying in the elementary education system.

Another library-related action is the federal government's free textbooks program for children that gives a set of books to schools, including those in private institutions, since 1958, although, in the beginning, it did not cover every school and the number of book titles was limited.^[29] The total number of volumes distributed in 2007 was a staggering 54,279,051 volumes.^[30] A subsidized and free textbook program also exists for high schools (Libros de Texto Gratuitos para Secundaria 149.480.757).^[29] The aim is to help students have and/or acquire their required readings. These book programs complement library services, although, as some critics say, it limits information literacy, because kids do not have to search for additional information beyond the compulsory textbook readings. However, this challenge is more due to the prevalent teacher-oriented pedagogical approach than to the free textbook programs. Teachers normally lack extensive reading habits themselves, which sometimes limit the potential academic impact of their classroom book collections and school libraries.

The reading programs in schools and libraries must overcome the limited reading habits of children, and, as stated, of teachers themselves, because basic education tends to be based on rote repetition, where the only source of information is usually the teacher. Teachers who fail to promote reading habits at the time when children learn to read and write waste part of the economic resources devoted to the school library sector. As a result, pupils finish school with limited or no information skills, posing a challenge at subsequent educational levels, where teachers or professors ought to be filling the information competencies gap. School information literacy challenges are reflected in the reading habits of society if one takes as a reading indicator the low number of bookstores, that only total around 1452 in the whole country.^[30]

SPECIAL LIBRARIES

Most of these libraries can be grouped into four clusters: 1) science and technology libraries, financed by the National Council of Science and Technology, or

CONACYT (Consejo Nacional de Ciencia y Tecnología); 2) research institute libraries, part of university research centers; 3) government libraries, mostly part of the ministries; and 4) special libraries that are part of private sector industries, service corporations, and/or museums, among other organizations. In the national directory of libraries published by CONACYT in 1976 special libraries were well-documented. Unfortunately this directory has not been updated, in part because these libraries lack an association or a central organization that could promote a directory. Current special libraries can be estimated at between 500 and 600, including academic specialized collections attached to universities. According to García,^[31] Mexico ranks second in the total number of special libraries, after Brazil in Latin America. According to Carrión,^[32] special libraries have had excellent development in recent decades. Their collections, funding, and professional staff are among the best. However, libraries, in the traditional sense of holding large printed collections and having purpose built buildings, have been decreasing in the last decade to give room to special information services that rely heavily on electronic sources and require fewer staff.

CONACYT has played an important role in special libraries expansion. The Council was founded in 1970 to foster, among other roles, the national research system, with the corresponding goal of creating a national information network. With such a mandate, the 1970s were a decade of increased special libraries creation. CONACYT intensively promoted library training, extending the benefit to university libraries. A special program was set up to send graduate students to study library and information science abroad, especially in the United States. The program lasted 5 years, and achieved the goal of training around 60 MLS professionals (1974–1979). Those who accepted positions in libraries pioneered a period of organization of special and academic libraries, especially outside Mexico City, where professional librarians were in great demand. In conjunction with the graduate program, a library technical staff program operated from 1973 to 1979. The training, involving a two-semester full-time study scheme, was excellent because it included all the subjects required to organize and provide library services. Participants from every state were invited, with the aid of a student CONACYT grant, to attend the program, mainly hosted by the National School of Librarianship and Archives, with a summer version offered once in Ciudad Juárez and Puebla. About 200 library staff personnel participated in the program. A contribution of the trained staff was the implementation of the first basis for a library organization outside Mexico City, where there were virtually no professional librarians, becoming the backbone of library development in those areas. The following sections include more information on special libraries by sub-type.

Science and Technology Libraries

This group of special libraries is closely related to the National Council of Science and Technology. The Council funds 26 basic science and science and technology research centers and their libraries, plus two social sciences institutions: El Colegio de México, and the Mexican unit of Latin American Faculty of Social Sciences, or FLACSO (Facultad Latinoamericana de Ciencias Sociales). This nation-wide science and technology library network subscribes jointly to electronic sources, and organizes an annual library meeting. The larger libraries are those of the Center for Scientific Research and Graduate Education of Ensenada, or CICESE (Centro de Información Científica y Educación Superior de Ensenada), the Research Center of Applied Chemistry, or CIQA (Centro de Investigación en Química Aplicada), and El Colegio de México, a social science think tank that has the largest bibliographic collection in Latin America. Some of these research centers have postgraduate programs focused on research training. Similar social science institutions focusing on local studies are replicated in some states. These institutions generally have good libraries not necessarily supported by CONACYT funding.

Research Institute Libraries

Research institute libraries that serve research communities/centers are also outstanding. UNAM, the national university, produces a great proportion of the national research output, an activity that relies on important specialized collections. Its special libraries number 52, of the total of 142 libraries.^[33] Their collections are in paper and in electronic format, and their library staff also number among the best. Additionally, most of the state universities also have special libraries, although fewer than UNAM. The better research institute libraries belong to the five larger universities from Guadalajara, Nuevo León, Puebla, Veracruz, and Universidad Metropolitana in Mexico City. As stated, the IPN, as discussed above, is the largest technological institute. It has 12 special libraries that support different areas of research. Another center with an excellent library is the Center of Advanced Studies and Research, or CINVESTAV (Centro de Investigaciones y de Estudios Avanzados), a center that was formerly part of the National Polytechnic Institute. At a national level, it probably has the largest science and technology collection housed under one roof, and includes some branch libraries in the regional research centers. The Postgraduate College of Chapingo (Colegio de Posgraduados de Chapingo), a specialized agricultural institution that networks with related institutions from other states, has the largest library in its field in Mexico. Private universities do not normally have special libraries, except for ITESM in business information, because, as mentioned, they are mainly teaching institutions with no research or minimal research output.

Government Libraries

Government libraries are, as might be expected, part of ministries, larger government official organizations, and part of federal and state departments. Many of the libraries have leading collections in their fields, such as those in the Foreign Relations Ministry (Secretaría de Relaciones Exteriores), and at the Treasury Ministry Library (Secretaría de Hacienda). The Mexican Congress Library, with legal deposit status, also has a good collection. Another is the National Institute of Anthropology and History, housing an outstanding collection, the largest in this field. Some of the government energy companies have research centers, normally with independent legal status, such as the Mexican Petroleum Institute, or IMP (Instituto Mexicano del Petróleo) that holds the major collection in the country on petroleum-related subjects, and the Institute of Electrical Research Institute (Instituto de Investigaciones Eléctricas) also an excellent information center with the best collection, resources and services in electricity, and secondarily in other energy subjects. A third library on atomic energy is the Institute of Nuclear Research (Instituto de Investigaciones Nucleares).^[34] Government statistics on population (census), geography, and macro-statistics are provided by the INEGI, originally founded in 1925. It recently received independent legal status from the government to ensure objectivity in its data gathering. It is in charge of the national census and with collecting most types of socio-economic data. INEGI has a network of 46 information centers, plus 560 deposit libraries. Health science libraries are well-developed, thanks to the Mexican Social Security Institute, or IMSS (Instituto Mexicano del Seguro Social). The IMSS has the largest public health network, serving employees and workers from the private sector. It has some of the largest hospitals, clinics and health care facilities, and its 57 libraries are often the only sources of medical information in the smaller cities. The Institute subscribes on a nationwide basis electronic sources, so that each center has similar access to information sources. The Ministry of Public Health has about 15 good libraries that serve the specialized research institutes (mostly based in Mexico City) conducting medical science research in fields such as oncology, genomics, nutrition, and children's health, among other fields. The judiciary system also has special library units in the different states, in the so-called Culture House (Casa de Cultura), along with the Supreme Court library in the national capital.

Private Libraries

The private sector, i.e., industry, service corporations, and businesses, among others, has fewer special libraries. Data about these libraries is difficult to obtain, but it can be said that some, not all, of the large corporate companies have libraries at their headquarters. The Mexican economy is

dependent on foreign corporations, mainly from the United States, and secondarily from European nations. Therefore, the branches located on Mexican soil seldom have information centers or libraries because these services are provided from the headquarters located outside Mexico. Additionally, the advent of electronic services has helped companies to reduce the number of private special libraries because it is now easier to transfer information across borders using seamless Internet and World Wide Web services. Those companies with libraries are mainly in the three largest cities, and, to a lesser extent, in the rest of the country. Some of the best examples are the libraries of the capital's newspapers: *Reforma*, *Excelsior*, *El Financiero*, and *La Jornada*; those in consulting firms, such as Mackenzie; in large law firms and major banks, and in companies like Grupo Condumex, which has a rich collection of historic Mexican publications.

NATIONAL LIBRARY INSTITUTIONS

The national duty of preserving the country's intellectual and cultural heritage is divided among several institutions. The main ones include the National Library that was founded in 1867, although the first law that unsuccessfully attempted to create it dates back to 1846. The first legal deposit decree to help the National Library to collect publications is from 1812, with successive updates since then up to the most recent one in 1991.^[35] The National Library was a government run institution up to 1929, when responsibility for it was turned over to the National University (UNAM) that manages and houses it in the main campus. The National Library also became part of the Institute of Bibliographic Research, or IIB (Instituto de Investigaciones Bibliográficas) in 1967. The IIB is divided into two departments, one for the National Library itself, devoted mainly to monographs, and the second for the National Serials Collection (Hemeroteca Nacional de México). The Institute has 26 researchers who are in charge of the national bibliography and other research programs. The two collections are housed in separate units within the same building. They were originally in a former Agustín temple in the historical center of Mexico City until 1979, when a new building was constructed to house them. The Library and the serials collection have the richest bibliographic jewels of the nation: incunabula from Mexico and Europe, unique Mexican monograph copies, and archives and manuscripts from Mexico's colonial period, i.e., fifteenth century, to publications of the twentieth century. These rare and special collections are probably the most important in the former New Spain vicerey cities of Latin America. The National Library collection numbers over 2,286,292 books and documents, including music records, videos, plus the reserved collections. The Library has, as it may be expected, closed stacks, but the study rooms are open to researchers and to the general

public. It also offers source cataloging to editors and publishes the national bibliography *Mexican Bibliography* (Bibliografía Mexicana), and allows the public to search their online catalog, called Nautilo. The serials library has two collections: the oldest, including titles from 1722 to 1916, and the contemporary titles. In recent years, it has been converting newspapers from several Mexican cities into digital format. The current digital collection has nine million images to date. This will be a major news source for researchers who live outside the national capital. Both institutions, unfortunately, lack the authority and resources that would be needed to guide acquisitions, technical and library service development for the rest of the libraries at the national level, as is the case in similar institutions in other countries. Their role is mainly to safeguard the national printed materials.

Other libraries use the term “National,” such as the central library of the National Polytechnic Institute (Instituto Politécnico Nacional) that specializes in science and technology materials, as well as the library of the National Institute of Anthropology (Instituto Nacional de Antropología). However the term does not really comply with their institutional roles, because they, again, lack a national library leadership or coordination role in their subjects of interest. The Library of the Mexican Congress (Biblioteca del Congreso, 1935) is also a legal deposit center. Its collection covers all subjects and includes rare books from 1511 to 1930, plus 66 manuscripts. In addition, Mexico also has similar organizations that preserve and collect movie reels at the Filmoteca (Films House), and government official archives at the General Archives of the Nation, described in the Archives section. Some Mexican states also have similar institutions.

VIRTUAL/DIGITAL LIBRARIES

Most, if not all, of the virtual libraries have been developed at universities. Only a few libraries include all four elements of the virtual library concept: electronic resources, digitization of materials, software infrastructure, and virtual library services. Most state university libraries and private university libraries subscribe to electronic databases but not all have federated search capabilities. Digitization of collections, mainly historical materials or non-copyrighted materials, is conducted at perhaps 25–30 institutions, including universities and research centers. The principal collections are UNAM’s nearly 40,000 digitized theses, Universidad de las Américas (Puebla)’s historical collections, Universidad Veracruzana’s historical archives and institutional journals, and the rare archives being digitized at the Universidad Autónoma de Ciudad Juárez, among other collections. In addition, the National Library and the National Serials Collection are undertaking, as stated, the digital conversion of microfilmed national newspapers to

digital formats. In terms of software, the first institution to acquire a federated search engine in Mexico and Latin America was the Universidad Veracruzana, in 2003. They also purchased virtual reference software (QuestionPoint),^[36] again making it the first library in the Latin American region to do so. Currently about 20 institutions have a search engine and fewer than that offer virtual reference services. The UNAM has worked on the development of an in-house meta search engine, called Hermes, that so far, is just for institutional use.

Repository management software, Personal Digital Libraries has been developed by the Tecnológico de Monterrey, but its use seems to be losing ground with the increased adoption of Dspace, the program created by the Massachusetts Institute of Technology. Another repository management software that is also used, but to a lesser degree, is Greenstone, developed by the New Zealand Digital Library Project at the University of Waikato, using UNESCO funding. A related open access journal repository, the Network of Scientific Magazines from Latin America, the Caribbean, Spain, and Portugal, or REDALyC (Red de Revistas Científicas de América Latina, el Caribe, España y Portugal), started in 2003, was created by the Autonomous University of the State of Mexico, UAEM (Universidad Autónoma del Estado de México). The system includes journals from Latin America, the Caribbean Region, Spain, and Portugal. It currently hosts more than 550 titles in all social and scientific areas with electronic holdings of 100,000 peer-reviewed articles in Spanish, Portuguese, and English. According to REDALyC’s official statistics, 70,000 articles are downloaded daily, a good indicator of success.

LIBRARY EDUCATION

Mexican library schools have graduated around 4500 librarians: 4300 with undergraduate degrees, 270 with master’s degrees and 15 with doctorates. This means that most professionals working in libraries do not hold a library degree. Those with library degrees work mainly at university and special libraries, because, as stated, school and public libraries seldom have professionals on their staff. There are 11 library and information science programs (see Appendix 2). The first school was founded as early as 1924, but it had its difficulties and closed. Later on, in 1945 was founded what is now the oldest running library School in Mexico City: the National School of Librarianship and Archives (Escuela Nacional de Biblioteconomía y Archivonomía) under the sponsorship of the Ministry of Public Education.^[37] The second oldest library school is at the National University (UNAM), also located in Mexico City (1956). These two were the only library schools until 1970, when new library schools were created in the succeeding years. Most institutions offer undergraduate programs, only three offer the master’s

degree, and just one, UNAM, offers a doctoral program (since 1998), the first one in Spanish-speaking Latin America. Among the programs, four offer distance education degrees, three undergraduate, and one offers a master's degree. Library schools and programs are basically located in the three major cities, except for four programs located in the rest of the country (see Appendix 2). Most schools include the name "library science", except for three that include the terms "documentation", "information science" and "knowledge management and information". Dissertations are required at some of the institutions. Several of the library schools lack a full-time faculty or have a minimum number of professors, except for UNAM, ENBA, SLP and Toluca that have more consolidated faculty. There are also library technical programs at the high school and college level in Mexico City. The newest at the college level, Técnico Superior Universitario, started in 2008 and is offered by the Universidad Veracruzana. Students in this program earn a library technical training certificate in 2 years. Continuing education is a common way to train professional staff. Courses are offered by library associations, the University Library Research Center, or CUIB (Centro Universitario de Investigaciones Bibliotecológicas) at UNAM, and some major libraries.

CUIB is the largest library research center in Latin America, founded in 1981, with a publishing output of 127 books, and the leading library journal in Mexico, as well as the best and largest library collection, and 25 full-time researchers, most of them with a doctorate and recognized by the National System of Researchers of the National Council of Science and Technology. Universities offer in-house "diplomados," informal training programs for their staff, which cover basic library subjects and run for some months.

ACCREDITATION—CROSS-BORDER HIRING OF LIBRARIANS

Although there are few librarians in Mexico, there are a number of librarians who cross the border to work in U.S. libraries. Their degrees are unfortunately not recognized by U.S. libraries because they do not come from library schools with American Library Association accreditation. Librarians who come from the United States and Mexicans who have graduated from library schools in America face the same challenge in Mexico. Their degrees are not fully recognized. Mexicans have the option of undergoing a long process to get government certification that includes complicated paper work from the Mexican Foreign Relations and the Public Education Ministry, and the National University's curriculum review. Most professionals avoid the process—even those who work at academic institutions, where the recognition of foreign library degrees is important for tenure. Librarians who immigrate

to the United States normally have to complete a master's degree in the library school field if they want to have the appropriate credentials required by the American library profession. This means that there is an international opportunity to create a library school accreditation agreement between Mexico, the United States and Canada. It would certainly benefit Mexican library school graduates, who could work on either side of the border with an accredited degree. Obviously this task is not easy, because library school programs may need to be aligned and recognized as comparable, that is, they may need to be similar, at least in the basic subjects that are the essence of library schools and information science. The North American countries, Canada, the United States, and Mexico, could follow the pattern of the European Bologna process, which is unifying library school education programs across Europe. Another alternative would be to recognize the accreditation process used in each of the countries.

Accreditation in Mexico is fairly new. The official external evaluation body, the Inter-institutional Committees for the Evaluation of Higher Education, or CIEES (Comités Inter-Institucionales de Evaluación de la Educación Superior) was created in 1991, and the Council for the Accreditation of Higher Education, or COPAES (Consejo Nacional de Educación Superior) dates from 2001. COPAES relies on professional associations, i.e., guilds, or what we call "College of Professionals" to conduct the whole process. Institutions whose programs undergo the evaluation can receive more federal funding and other benefits from the Ministry of Public Education. Library schools and the Mexican Library Association have been slow in pushing for a full accreditation program beyond the evaluation review that they currently undergo. The body that could potentially play the role of accrediting agency for library schools is the National Librarians Guild or CNB (Colegio Nacional de Bibliotecarios), the professional librarian guild in the country. Unfortunately, it is a small organization, currently without the means to fully undertake this role, crucial to increasing the quality of library education in Mexico. There is an accredited library school, the UAEM. However, it received its certification from a social sciences organization; therefore it is not a library body. In conjunction with our library associations, the North American Free Trade Agreement (NAFTA) provides the opportunity to create an accreditation system for the three countries, the United States, Mexico, and Canada, or at least to establish some type of recognition for North American cross-border degrees.

THE U.S. PATTERN

Library science and its practice in Mexico are based on U.S. library principles. For example, university libraries in Mexico use the U.S. Library of Congress Classification

system, while public libraries use the Dewey Decimal System, and all libraries that have a bibliographic organization use Anglo-American Cataloguing Rules. There are reasons for these facts: the first librarians to get training went to the US to get their degrees in the early 1920s, and into the seventies, when Mexico established an ambitious library program for academic librarians that launched library development. There were, as mentioned earlier (See Special Libraries section), several tens of scholarships being granted to students to go to the United States to obtain a master's degree in library science or information science. The main library schools that received these students were the University of Texas at Austin, and later the universities of Syracuse, Cleveland, and Denver. The last major group, 23 people, to get a library master's degree at a U.S. library school (University of Wisconsin at Milwaukee), was financed by the ITESM. In addition to these programs, the US has also granted scholarships to several students through the Fulbright program. An institution that additionally has played a key role in promoting library principles is the Benjamin Franklin Library, the official information center of the United States Embassy in Mexico City. Inaugurated in 1942, this was the first public library created by the American government outside the United States, and of the few full-sized libraries to remain after recent government downsizing. Many professionals, mainly from Mexico City, had their first library experiences at this library, either as reference assistants or student assistants. Some later became professional librarians, by getting scholarships to obtain a degree in the United States. Between the 1960s and the 1970s, the Franklin Library was one of the best public libraries in Mexico City, and thus a model followed by other institutions in the capital of the country.

SERIALS

The text of this section is an extract from a paper devoted to serials by the author.^[38] The oldest circulating serials in Mexico date back to the 1800s, such as *Bulletin, Mexican Society of Geography and Statistics* (Boletín, Sociedad Mexicana de Geografía y Estadística) (1839, ISSN 0188-1442), *Medical Newspaper of Mexico* (Gaceta Médica de México) (1864, ISSN 0016-3813), and *Yearbook of the National Astronomic Observatory* (Anuario del Observatorio Astronómico Nacional) (1881). However, the first serials appeared in Mexico in the 1700s, such as *Literary Newspaper of Mexico* (Diario Literario de México) (1766), *Mercury Flyer* (Mercurio Volante, the first medical magazine in America) (1772–1773), and *Varied Issues on Science and Arts* (Asuntos Varios sobre Ciencias y Artes) (1772–1773). These serials were the first in the American continent.^[39] The International Standard Serial Number Agency (ISSN) reports 3431 Mexican periodicals,^[40] although it is estimated that there are

at least twice as many, due to the fact that many periodicals lack ISSN registration.^[41] Journals are, in general, published by state universities and by national research centers financed by the government (usually the federal government). Subject coverage of journals is wide, covering most disciplines and subjects. However the strength is in the social sciences and the humanities, where 60% of the production is published.^[41] There is also a significant number of cultural periodicals, like those from other countries. Mexican serials are the best sources for updated academic and scientific information because they publish the best output of researchers and writers. Electronic journals are emerging in good numbers; with some now only published in electronic versions. Library serials number about 10 depending on how one classifies them; several titles have appeared only for short time spans (see Appendix 3).

In terms of comics and magazines, Mexico has a significant number of these, with large audiences. Some of the most popular titles can reach nearly a million copies per week.^[42] These periodicals play an important role in fostering reading habits among those who have only a few years of schooling, and even among those who did not have the chance to attend school. Comics are also a huge export to the United States, where Hispanic communities also love to read cowboy and soap opera style stories. As it may be assumed, these serials are the business of private companies who publish numerous titles covering a variety of topics.

Newspapers, on the other hand, have a market usually divided into four tiers according to the geographical locations where the papers are published, a fact that correlates with the importance of the newspapers. First are the dailies from Mexico City. They dominate the market, because of their broader coverage and a good nation-wide distribution system, in addition to being the news agencies for smaller papers. Second in importance are the dailies from the two other major cities, Guadalajara and Monterrey. Both locations have succeeded in distributing their papers to the rest of the major cities. Third are the papers from the medium-sized cities, usually state capitals. They tend to have a distribution limited to the state borders and normally have good publishing facilities. Finally, the fourth tier of newspapers consists of the local community dailies. These periodicals are simple and modest, covering political subjects and local topics relevant to their communities. Many of them struggle to survive with limited resources. Some of the local papers are part of national editing companies, relying on their editorials for in-depth articles. Editing of newspapers from the first three tiers has improved over time. Currently, titles from the largest cities are edited electronically and posted on the Web, some publishing full articles and others putting out only summaries of their main news in their Internet versions.

BOOK PUBLISHING

As stated in the first section of the paper, Mexico was the first country in America to have a printing press in the sixteenth century. This means that Mexico probably has the greatest number of American incunabula that is found at the national library and at some university libraries. Nowadays publishing is an important economic activity, and it is one of the most important in the Latin American region. The other countries that also have a good production are Colombia and Argentina that compete in production. The Mexican book trade is mainly based in Mexico City, where most of the big American and European publishing houses have subsidiaries, plus national companies. After the Spanish civil war several editors migrated to Mexico and contributed to strengthen this industry. Mexican book production covers most subjects but the main output is devoted to basic education, where most of the volumes are printed, according to the statistics of the National Chamber of the Mexican Publishing Industry, CANIEM (Cámara Nacional de la Industria Editorial Mexicana). The country produced 18,682 titles in 2006 according to CANIEM. The production is devoted mainly to basic education (22%), literature (14%), science and technology (12%), and the rest to other subjects, including children books that stand out with 10% of the total publishing output. In terms of copies, basic education gets almost half of the total output with 47.3%, and children books get 20% of all the copies printed. The rest of the production is scattered in the several subjects, such as literature, languages, and philosophy, and psychology. Most of the printing production is, on the other hand, represented by reprintings of titles with 58.6%, new titles by 32.4%, and reeditions with 9%. This amounts 109 million copies.^[30] The main costumer for publishers is the Mexican government with the free textbook program, and the acquisition of books for school libraries that was described in the section in earlier sections of this paper.

INFORMATION VENDORS

The proximity to the United States has made Mexico an attractive place for some American and other information vendors to set up offices. For some vendors, like EBSCO and OCLC, after Brazil, Mexico is the second largest library and information market. Companies that have established regional offices, in addition to the two corporations just mentioned, are Swets, Aleph, and Cengage. Other major international companies have local offices to cover the national market. The local information industry has steadily evolved in the last two decades. Business information is a thriving sector, growing faster than information services to the academic community. Information aggregators tend to focus on business information. Some

were originally Mexican start-up companies that were later acquired by major overseas companies, such as Infolatina, that was bought by an American information aggregator. Some important information companies in the country are Mercamétrica (directories), IBCON (directories), El Financiero (financial information), and Reforma (syndicated news). Information services are also provided by chambers of commerce. Several of these organizations offer information services to companies and the government. Computer-integrated library systems, on the other hand, probably represent the larger segment in Spanish-speaking Latin America. The most popular one continues to be the Automated System for the Integration of Libraries of the University of Colima, or SIABUC (Sistema Integral Automatizado de Bibliotecas de la Universidad de Colima) created by the University of Colima, which has given away 1500 copies of the software in Latin America, according to a report provided by the institution. This software is nearly free; it requires just a minimum fee of fewer than \$2000 for the original acquisition. Additionally, there are at least four companies that have created integral library systems for sale and distribution in Mexico and throughout the region, such as Altair and Janium.^[43,44]

LIBRARY ASSOCIATIONS

Library associations date back to 1924, when the first one was founded. The first library conferences were organized in 1927 and 1928. This early association experienced difficulties, not becoming a formal association until 1954, then gaining legal recognition 2 years later, when it adopted the official name of the Mexican Association of Librarians, or AMBAC (Asociación Mexicana de Bibliotecarios, Acción Civil). AMBAC is recognized as the national library association and is headquartered in Mexico City. Since 1956, it has run the largest library conference, an event that became annual in 1977. The conference includes a major vendor exhibition, and its proceedings have been an important source of library literature for many years. It also publishes a quarterly newsletter *News from AMBAC* (Noticiero de AMBAC) that is the oldest continuously published library serial in the country (see Appendix 3). The association has subject sections, with current ones in arts, reading, national information policies, public libraries, school libraries, and information literacy. AMBAC formerly had geographical sections in some of the Mexican states, but they became independent associations when a tax reform affected the fiscal management of AMBAC. The states with associations are Baja California, Chihuahua, Jalisco, Michoacán, and Yucatán. In recent years, AMBAC has been trying to create geographical sections again, but Nuevo León is the only one in existence so far, although three more are in the

process of formation. AMBAC does provide some support to the local library associations who continue to view it as their parent organization. The split with state associations has meant that AMBAC membership has not grown and still numbers about 500.

The second most important professional association, although small, is the CNB founded in 1979 in Mexico City. This body only includes librarians who have obtained a university degree. The CNB has, by law, the right to advise government and to conduct evaluation and accreditation processes in library schools because guilds are officially bodies that represent their professional discipline. In addition to CNB, there is the National Council of Library Affairs of Higher Education Institutions, or CONPAB-IES (Consejo Nacional para Asuntos Bibliotecarios de Instituciones de Educación Superior), described in the university libraries section. Some other associations have existed previously, like the Association of Libraries and Institutions of Higher Education and Research, or ABIESI (Asociación de Bibliotecas e Instituciones de Educación Superior y de Investigación), created in 1967, and disbanded in the 1990s. This association's main contribution was the publication of the interlibrary loan code and a set of library standards that are still quoted in the literature. Other short-lived associations, in existence for fewer than two decades have been in the fields of agriculture: the National Association of Agricultural Librarians ANBAGRO (Asociación Nacional de Bibliotecarios Agrícolas); government: Association of Librarians of Governmental Institutions of Mexico, or ABIGMAC (Asociación de Bibliotecarios de Instituciones Gubernamentales de México); and in the field of biomedicine: the Association of Librarians in Biomedicine, or BIBAC (Asociación de Bibliotecarios en Biomedicina), among other bodies. The life and activity of state associations is linked to the size of the library profession in the Mexican provinces, where, unlike in Mexico City, professional librarians are just a handful. The arrival of new library schools in some of the states may foster a local library association development. Generally, library associations and some leading library systems host annual library conferences on general and specialized subjects. These programs are probably the second, if not the premiere, conference offerings in Latin America (see Appendix 4).

INTERNATIONAL LIBRARY COOPERATION

With the most visible international activities, academic libraries lead in collaboration. The most extensive cooperation activity is with U.S. organizations, and to a lesser degree with Latin American and European countries. Mexican border universities often have strong collaborative ties with their counterparts on the other side of the border. For example, the Universidad Autónoma de Ciudad Juárez has borrowing agreements with New Mexico State University

and with El Paso Community College, and the CICESE in Ensenada, Baja California, has cooperative agreements with the La Jolla Scripps Research Institute in San Diego. In addition to the academic institutions, the Mexican Library Association has strong links with its international counterparts from Latin American, under the International Federation of Library Associations and Institutions, as well as the principal U.S. library associations that include the American Library Association, the Special Libraries Association, and REFORMA (who have opened paths for cooperation), as well as some state organizations. Cooperation takes the form of visiting speakers attending annual conferences, facilitation of workshops, staff exchanges, and materials exchange. Seal produced an excellent paper documenting U.S.–Mexico collaboration.^[45] The best communication venue for U.S.–Mexico cooperation is the FORO, Transborder Library Forum, where some Canadians have also participated, the meeting that began as an annual event in 1991 became, after a decade, a bi-annual conference.^[46] It alternates between Mexico and the United States. The FORO was originally organized as a reaction to the NAFTA agreement to strengthen the relationships among border libraries. One of the FORO's byproducts is the multilateral interlibrary loan project between U.S. universities and central Mexican institutions, with the Franklin Library playing a key role facilitating the shipment of bibliographic materials by diplomatic pouch.

ARCHIVES

Like libraries, archives began, in the western sense, after the Spanish conquest of Mexico. Archives were formed during the colonial era in monasteries and churches where registration births, deaths, and property transactions took place. Civic life was directed, in many ways, by the Catholic Church until the nineteenth century. The best source of Mexico's colonial history is the Archives of Indies in Seville, Spain, where the most important records of colonial life are stored. The government had split from the Catholic Church in 1855, creating the national birth registry, when Benito Juárez, then president and a great political reformer, opened the registry office in Veracruz, and the first birth certificate was issued to his daughter in 1859. Several archives of churches and religious groups passed to other government organizations or to especially created archival institutions. The main archive is the General Archives of the Nation, or AGN (Archivos Generales de la Nación), located at the former Lecumberri Prison in Mexico City, where cells now hold different sections of the file collection. The AGN is the leading organization in archives policies and filing standards, with its own organization scheme followed by several archives in the country. Most states have an archive system or structure that coordinates those in the municipalities. Among them

are the property offices in each city. They make copies of their documentation to be sent to the state capital's general archives. A similar pattern is followed by birth registries. The new law on information transparency is improving, and will continue to improve, archives, because all government ministries, departments, and official bodies, including public universities, have to include organized archives and make them available to the public via the Web. The body in charge of implementing policies and supervising the legal implementations is the Federal Institute of Information Access.

There are several historical archives located in the large urban centers, mainly those with a colonial past. A survey conducted in 2007 by the Association to Support the Development of Archives and Libraries, or ADABI (Asociación de Apoyo al Desarrollo de Archivos y Bibliotecas en México, AC) identified 142 archives, but this number only corresponds to those that have printed inventory catalogs. The survey classified them in the following categories: 75 parochial archives, mainly from the Catholic Church; 53 state and county archives (included historical and administrative archives); and 14 historical archives covering colonial, independence and revolution materials.^[47] The 12 most important private archives are in Campeche, Mexico City, Oaxaca, Puebla, Tamaulipas, and Yucatán. One diocesan archive was reported in the State of Guerrero, in the Southwestern part of the country. Presumably, the archives reported in this study are well-managed, if it is assumed that those who answered have organized archives. However, the total number of historical archives throughout the country may be 3 times this figure. Another study attempting to identify how modern archives were in terms of their organization and storage estimated that 67% of them have a budget that is lower than \$25,000 and 10% have budgets of fewer than \$100,000 annually. Additional findings were that 85% of the archives have internal regulations and security measures, and 29% have temperature and humidity control systems, and 85% have computers. Most of the archives, 85%, are open to the public. The results of the study are, in general, positive.^[48] There are three archive associations, included the one mentioned above, ADABI. This association organizes conferences and meetings and is probably the largest. Two other are the Mexican Association of Libraries and Institutions with Old Collections, AMBIFA (Asociación Mexicana de Bibliotecas e Instituciones de Fondos Antiguos), and the Mexican Association of Private Archives and Libraries, AMABPAC (Asociación Mexicana de Archivos y Bibliotecas Privados, AC). All of these associations have Web sites with membership information. Only two academic institutions offer undergraduate archives studies, they are the National School of Librarianship and Archival Science, or ENBA (Escuela Nacional de Biblioteconomía y Archivonomía) and the Universidad de San Luis Potosí. The first is the older one and has 862 graduates, while the second has just started awarding baccalaureate degrees in archives or records management.

MUSEUMS

Like other institutions discussed in this entry, the organization, collections and economic resources of the 1137 Mexican museums are closely related to the size of the city where they are located. Mexico City ranks number one, with the largest number of museums and with most of the best collections, followed by Guadalajara and Monterrey. The rest of the state capitals have an average of four museums, plus those in the rest of each state outside these capitals. Museums have increased substantially since the beginning of the last century (1907) when there were 38, according to the Mexican Association of Museum Professionals, or AMProm (Asociación Mexicana de Profesionales de Museos).^[49] It is also estimated that 60% of the museums are devoted to anthropology and history, 25% to fine arts, and 10% to science and technology, plus other subjects, including children's museums, accounting for about 1%. Along with the classical twentieth century concept of museums, there are also zoos, aquariums, and natural reserves that are not discussed in this paper.

Museums are created and managed by different bodies, including the federal, state, and municipal governments, communities, the private sector, and companies or individuals. The National Institute of Anthropology and History, or INAH (Instituto Nacional de Antropología e Historia),^[50] is probably the largest organization that manages museums, 244. It groups museums into six main categories:

1. National museums have country-wide collections and are located in Mexico City. The largest and the best INAH museum is the Anthropology museum that holds some of the most valuable collections of Mexican indigenous cultures.
2. Regional museums cover more than one state and are located in different parts of the country. A good example is the Museum of Cultures (Museo de las Culturas) in Oaxaca.
3. Local museums that are in historical buildings or that hold different collections, such as the Customs House of Ciudad Juárez (Ex-Aduana).
4. Community center museums, such as the outstanding Convent of Tepoztlán (Ex-Convento de Tepoztlán).
5. Community museums hold collections, usually of archeological artifacts, valued by communities.
6. In situ museums whose collections are in archeological sites, where artifacts and information are derived from the same grounds. The most outstanding ones are Chichen-Itza, the Teotihuacan Pyramids, and Uxmal.

The states with the largest numbers of museums, outside Mexico City, include Jalisco with 54 (where Guadalajara is the capital), Veracruz with 18, and Chiapas has the largest number of community museums, 35.

The second organization managing museums is the CONACULTA. This federal governmental body manages 132 museums and galleries. The best are in the Palace of Fine Arts (Palacio de Bellas Artes). Another federal organization that takes care of museums and art galleries is the National Institute of Fine Arts, or INBA (Instituto Nacional de Bellas Artes).^[51] It has some excellent museums like National Museum of San Carlos; the Museum of Modern Art and the Tamayo Collection. Private museums run by individuals, companies, and foundations are generally small, however, there are some fine examples of good-sized collections and notable buildings, such as the bank BANAMEX and the Franz Mayer Museum.

Some of the best museums in Mexico City for the general tourist, regardless of the body that manages them, are the mentioned National Museum of Anthropology, Modern Art, Tamayo, National Museum of Fine Arts (Museo Nacional de Arte), and the Papalote (a children's interactive science museum). Smaller thriving museums of interest in the capital include the Frida Kahlo, the Dolores Olmedo Museum that houses Riveras' works and the largest collection of Kahlo's paintings, and the private Franz Mayer Museum for the decorative arts. Guadalajara, the second largest city, also offers some good museums of interest to the outside visitor such as the Regional Museum of Guadalajara and the Popular Arts Museum (Museo de Artes Populares). Guadalajara has undertaken a project to build a Guggenheim museum. A group of private investors paid for a two million dollar feasibility study and the state government financed a call for an architectural building design contest. The planned premises are in a beautiful canyon rim in the outskirts of the city. This initiative may have behind it the idea of competing with Monterrey, located in Northern Mexico, where a cultural corridor has been created in the heart of the city flanked by first class museums, making it the second

cultural capital in the country. Its most outstanding museums and galleries are the Contemporary Art Museum, or MARCO (Museo de Arte Contemporáneo), the Museum of Mexican History (Museo de Historia Mexicana), and the Glass Museum (Museo del Vidrio), each housing excellent collections. The rest of the state capitals have fewer collections of smaller size and less financial support. Although there are some that are outstanding, such as the described archeological museums of Oaxaca and Veracruz (see Fig. 6).

Additionally, Mexican archeological sites number in the thousands, and they are certainly living museums. If the sites are lumped together with historical places, the number is 110,442. The challenges of cataloging them are great: 60% are cataloged or are in process, and 173 of them are open to the public, with nearly 10 million visitors per year.^[50] The top archeological sites are Mayan—Tulum, and Palenque in addition to those listed—plus the Zapotecan Monte Alban and Mitla in Oaxaca, the Totonaca site Tajin in Veracruz, and the Aztec Temple Mayor in Mexico City, and finally, the Olmec culture, the earliest known Mexican civilization, that dates back to 3000 years ago with the Tres Zapotes site.

A great feature of Mexican art is the muralist plastic movement that took place after the Mexican Revolution (1921), a time when Mexican identity was redefined. It was basically a nationalistic movement that focused on the indigenous people and on criticism of Spanish and foreign influences. The best-known include David Alfaro Siqueiros, Diego Rivera, José Clemente Orozco, and Juan O'Gorman, among others. Locations with murals in Mexico City by these muralists and those of their followers include the National Palace (Palacio Nacional), the Palace of Fine Arts (Palacio de Bellas Artes), the Central Library at UNAM, and the San Ildelfonso Museum (Museo de San Ildelfonso), among others. There are also murals in the rest of the states.

Fig. 6 Museum of Anthropology, Xalapa, Veracruz—by Héctor Nava.

The best, normally the larger museums, have libraries, such as the National Museum of Art, or MUNAL (Museo Nacional de Arte), Interactive Museum of Economy, or MIDE (Museo Interactivo de Economía), the Museum of Light (Museo de la Luz), and the National Museum of Anthropology (Museo Nacional de Antropología) in Mexico City, and the Museum of Mexican History (Museo de Historia Mexicana) in Monterrey. It is estimated that about 50 museums have libraries. The most outstanding is the large National Library of Anthropology and History attached to the museum of the same name, mentioned in the Special Libraries section of this entry.^[52]

Professionals working in museums have degrees in other fields, because there are very few options to get a university degree in this specific subject. The only public university that has a related program for museum professionals at Baccalaureate, Master and Doctorate is UNAM. The studies are in history of art. Additionally, one private university offers a program in the same field and two more on cultural promotion. None of these programs are specifically designed for museum management, but do give the basic background in art. Another option for museum staff is training through courses and workshops organized by the museums themselves and universities and are mainly held in Mexico City.

CONCLUSIONS

This overview of libraries, museums, and archives is just a snapshot because it is difficult to portray the country that

is large and has great differences between big and small cities, as well as between urban and rural regions. In conclusion, Mexico has some of the best libraries in Latin America; however, their development is uneven. In terms of growth and quality of library services, state university libraries and large private higher education institutions are in the leaders. However, at the bottom are several smaller public and private academic institutions that lag behind. Special libraries are also among the best libraries with good budgets, collections, and professional staff, but several companies fail to provide information services as part of their organizational structure. The public library system is the largest in Latin America and its growth and improvement has been indeed, a major achievement in the last 25 years. Its collection development is centralized in Mexico City but buildings and staff are the responsibility of the states and the municipalities. School libraries on the other hand, are few, considering the large number of primary and secondary education schools in Mexico, but the government has invested heavily in creating classroom collections, distributing more than 200 million volumes in the last 7 years. Because the number of librarians is inadequate, the country would benefit from more library school graduates. The national information institutions, such as the national library, and the national serials collection have good bibliographic treasures of colonial and contemporary Mexico, but their leading role is limited. There are many museums in Mexico, most of them are devoted to anthropology due to the great interest in pre-Columbian history. The largest number of museums is concentrated in Mexico City and the two other major cities

Appendix 1: Library Chronology

Year	Event
1400	Amoxcalli-Aztec codex (Amoxltli) libraries
1511	First book arrives in Mexico from Europe
1539	First printing press
1555	First book printed in Mexico—Alonso de Molina <i>Vocabulario en lengua castellana y mexicana</i>
1788	Opening of the first public library—Turriana Library
1790	First copyright law
1790	Foundation of the first Museum of Natural History
1790	Foundation of the National Archives—Archivo General de la Nación (Original name: Archivo General de la Nueva España)
1825	Foundation of the Mexican National Museum
1867	First decree to create the National Library—Biblioteca Nacional
1882	National Institute of Statistics, Geography, and Informatics (Originally as Dirección, Geografía y Estadística, DGE)—Instituto Nacional de Estadística, Geografía e Informática
1910	Opening of the National Museum of Archeology, History, and Ethnography (formerly known as the Mexican National Museum)
1921	First Department of Public Libraries, Ministry of Public Education—Dirección de Bibliotecas Populares
1922	First public library building—Biblioteca Pública Cervantes
1924/1954	Mexican Association of Librarians—Asociación Mexicana de Bibliotecarios, AC
1939	Foundation of the National Institute of Anthropology and History
1940	The National Museum of Archeology, History, and Ethnography changed its name to National Museum of Anthropology
1945	National School of Library and Archive Sciences—Escuela Nacional de Biblioteconomía y Archivonomía
1956	Opening of the UNAM Central Library Building—Biblioteca Central UNAM

(Continued)

Appendix 1: Library Chronology *(Continued)*

Year	Event
1957	First national library conference—Jornadas Mexicanas de Biblioteconomía, organized annually since 1974
1970	Foundation of the National Council of Science and Technology (An early funding body for special and university libraries)—Consejo Nacional de Ciencia y Tecnología
1970	Labor unions take power at academic libraries, and at universities in general
1972	First library science master's degree—UNAM
1975	First academic library building of a technological institute—IT Saltillo
1978	First Mexican integral (mainframe) library system—LIBRUNAM, UNAM
1983	First release of the library software SIABUC (Most popular free library software)—Universidad de Colima
1984	Foundation of the National Council for Academic Libraries—CONPAB-IES, Consejo Nacional de Asuntos Bibliotecarios de Instituciones de Educación Superior
1988	First librarian to get a Ph.D. (From the United States)—Jaime Pontigo
1999	UNAM Ph.D. program started—UNAM
2003	Mexican Information Literacy Standards are approved for higher education

Modeling Documents in Their Context

Airi Salminen

Department of Computer Science and Information Systems, University of Jyväskylä, Jyväskylä, Finland

Abstract

This entry describes notions and methods for analyzing and modeling documents in an organizational context. A model for the analysis process is provided and methods for data gathering, modeling, and user needs analysis described. The methods have been originally developed and tested during document standardization activities carried out in the Finnish Parliament and ministries. Later the methods have been adopted and adapted in other Finnish organizations in their document management development projects. The methods are intended especially for cases where the goal is to develop an Extensible Markup Language (XML)-based solution for document management. This entry emphasizes the importance of analyzing and describing documents in their organizational context.

INTRODUCTION

Documents serve in organizations as an important means for communication, as a vehicle in work processes, and as organizational memory. Often they are also needed as evidence of the activities in the work processes. The creation and utilization of documents is currently strongly technology-dependent. Documents are created as *digital* documents and software applications are needed to find documents and information available in them. Information in digital documents is lost if the documents cannot be found, if they cannot be presented to human perception, or if they cannot be understood. Understanding the meaning of documents requires, not only understanding the content of the documents, but also understanding at least to some extent the structure of the documents as well as the context where the documents have been created. The importance of the contextual information has been often pointed out especially in the work done on records management and archival research (e.g., McKemmish^[1]).

Many enterprises have begun major projects to turn their electronic document management (EDM) environments into environments with more standardized information structures and more effective and secure utilization capabilities. Developing systematic management of digital documents in an organization always requires some kind of standardization, that is, agreeing upon rules for the ways information is presented in documents, in particular, how the content of the documents is structured from information items. If the structure is indicated in the documents in a formal way, software applications can be used to process the documents as a collection of information structures. One approach to indicate the structures in documents is to use some markup language. Extensible Markup Language (XML) is the metalanguage currently widely used to define markup languages for particular

needs and to present information in documents in the particular markup language.^[2,3] XML is a restricted form of the older markup language called Standard Generalized Markup Language (SGML^[4]). XML was developed to offer special support for documents to be distributed over the Internet. The huge number of XML-related development activities initiated after the publication of the first version of XML as a recommendation of the World Wide Web Consortium (W3C) in 1998 shows that XML is becoming a kind of *lingua franca* for the data of the Internet.

In EDM reengineering and standardization projects of organizations, a profound analysis of the document management in the environment is needed. In such an analysis, current documents and document management practices are studied and described and new document structures and document management practices are proposed. It should not be restricted to analyzing document structures and describing them by more or less formal models. To be able to gather the important contextual information, analysis and description of the whole environment is needed. The primary concern in the analysis may be in the documents produced within the organization. EDM development can however also be important in cases in which there is little internal document production. For example, libraries interested in improving the quality of their digital library services need rather profound analysis concerning both the primary documents created outside the library and the secondary documents created within the library, which contain meta information about the primary documents. A library can also participate in an EDM development project as an expert on reader needs. For example, in the document standardization activities of the Finnish Parliament and ministries, the Library of Parliament has provided valuable information about readers of documents and reader needs.^[5]

This entry describes notions and methods for analyzing and modeling documents in an organizational context. The methods have been originally developed and tested during document standardization activities carried out in the Finnish Parliament and ministries. The implemented standards in the environment concern a major portion of the Finnish parliamentary documents. Later the methods have been adopted and adapted in other Finnish organizations in their document management development projects. The methods have been earlier introduced in Tiitinen–Salminen,^[5–10] and experiences of use cases have been reported in Salminen–Nurmekselä.^[11–16]

EDM CONCEPTS

In EDM development and document standardization, organizations are interested in documents as a means of information management: a means to cluster, organize, store, and transfer information. In particular they are interested in using computers and the digital form effectively. There is therefore a need for associated hardware and software to process the data of documents and to present the content for human perception. When the notion of information is understood according to the sense-making theory of Dervin^[17] as “the sense created in a situation, at a specific moment in time and space by a reader” (where Dervin means a human reader), then the information in a document is always subjective. In this entry, the following characteristics are regarded as essential to a *document*:

- It is intended for human perception, to be understood as information pertaining to a topic.
- It has content and one or more external representations.
- The content consists of parts, parts consist of symbols, parts are structured to support human understanding.
- It is stored on media.
- It can be identified and handled as a unit.

Additional characteristics of a *digital document* are

- The content is stored on digital media.
- The document is associated with hardware and software that can identify from the digital content the symbols and the structure of the parts and produce from them external representation to be perceived by humans.

Electronic document management in an enterprise does not concern documents only. Fig. 1 shows the major EDM components. There are basically two types of entities in an EDM environment: activities and resources. An *activity* is a set of actions performed by one or more actors. The *resources* are of three different types: actors, documents and related metadata, and systems. An *actor* is an organization or a person. *Systems* consist of devices,

Fig. 1 Components of an EDM environment.

Source: Adapted from Methodology for document analysis, by A. Salminen. In *Encyclopedia of Library and Information Science*, Marcel Dekker, Inc., New York, 2000.^[9]

software, and data used to support the performance of activities. Out of all the recorded data in an environment, documents are those possessing the characteristics listed above. The *metadata* describes the content, structure, and context of documents.^[18] The contextual metadata includes, for example, information about the actors, activities, and systems in the EDM environment. The broken lines in Fig. 1 show the information flow between activities and resources. Resources are regarded as information repositories in which the information produced in an activity can be stored or from which information can be taken and used in an activity. Information needed and produced during activities is stored in documents and in the related metadata, in the heads and experience of people, in the organizational culture, and in systems. *Information* is thus anything that can be stored in a repository and used in an activity, or that can be produced by an activity and stored in a repository to be later used in an activity (probably in some other environment). In relationship to documents and systems, actors are called *users*. The EDM environments in which a specific organization or person is involved may be quite complex, and the information in an activity making sense to a human actor often comes from many different sources.

XML STANDARDIZATION

Some kind of document analysis is needed in all major document management improvement efforts. Especially SGML/XML standardization has shown to be in some cases a complicated and demanding task. It may take several years, cause tremendous costs, and lead to various effects in the implementing organization as well as in its relationships to other organizations.^[11,12,19] On the other hand, also reasonably fast implementation cases have been reported during the last years.^[16,20] Experiences in the standardization of the Finnish parliamentary documents have shown the importance of careful analysis of the whole document management environment in the beginning of the standardization.^[11,12]

XML as Document Format

SGML and XML offer means for defining and representing information as *structured documents*. Compared to SGML, XML has a smaller set of rules, less optional features, and the referencing mechanism is planned especially for referencing to Internet resources. The logical structure of an XML document is described as a hierarchy of named elements and the elements are indicated by explicit markup. Elements can be associated with attributes to add semantic information. Both SGML and XML are metalanguages, not specifying a specific markup vocabulary or document structure but allowing the definition of specific markup languages for specific purposes.

A characteristic feature to structured document management is that the structure definitions, document instances, and layout specifications can be managed as separate content items. When XML is adopted for structured documents, the structure definitions are called *XML schemas*. Various definition languages have been developed for describing the schemas. Most important of them are the *Document Type Definition* (DTD) mechanism introduced as a part of the XML language^[2,3] and the XML Schema language.^[21]

Standardization Levels

Development and implementation of specific XML-based languages is part of the multilevel standardization activities going on around the world. Three major interrelated levels of those activities can be identified:

Universal standardization. At this level general rules for wide use for different application areas are developed. The universal standardization activities are coordinated by W3C. Examples of the universal specifications are the XML Linking Language (XLink) intended for describing links between resources^[22] and XSLT intended for describing transformations of XML documents.^[23] The development work on XML itself is part of the universal standardization activities.

Sectoral standardization. At this level rules for the purposes of a specific sector or application domain are defined. The rules are built on top of the universal rules and they are not necessarily intended to be implemented as such but to be used to tailor further specifications at the local standardization level. The developer is often a consortium of organizations of a specific sector but it may also be a person or a single organization, for example, a software company. W3C and ISO have also published specifications for specific purposes. For example, W3C has developed the XML-based XHTML for Web publishing,^[24] and the Text Encoding Initiative (TEI) Consortium participated by

several humanistic organizations has published guidelines for encoding electronic texts for scholarly research.^[25] The original TEI guidelines were originally based on SGML, later the guidelines have been adapted to XML.

Local standardization. At this level rules for a specific environment are developed. The standardization does not concern documents of the environment only, it concerns also the work of people, technology to be used for working with documents and for using documents, and the ways people of the environment collaborate with each other.

At all levels standardization is a continuing process. The changes in information technology, in organizations, and in business opportunities cause needs to update earlier specifications and to develop new ones. Furthermore, since the specifications are dependent on other specifications, changes in one specification cause needs to change other specifications.

An Example of Local Level Standardization

The SGML/XML standardization of documents produced in the Finnish parliament and ministries is an example of local level standardization. The standardization was initiated by a document analysis carried out in a project called RASKE. The term RASKE comes from the Finnish words “Rakenteisten AsiakirjaStandardien KEhittäminen” meaning the development of standards for structured documents. The methods developed in the project have later been called as RASKE methods. The project was commenced in spring 1994 by the Finnish Parliament and a software company in cooperation with researchers at the University of Jyväskylä.^[6] The Ministry of Foreign Affairs, the Ministry of Finance, the prime minister’s office, and a publishing house also participated in the project.

Starting the standardization was motivated by document management problems in the Finnish Parliament and government, for example, incompatibilities of systems, disturbing inconsistencies in the document contents, uncertainty concerning the future usability of the information in the archived digital documents, and unsatisfactory retrieval techniques.^[6] The document analysis concerned four domains: the inquiry process, national legislative work, Finnish participation in European Union legislative work, and the creation of the state budget. Preliminary DTDs were designed for 21 document types, including, for example, government bill, government decision, government communication, private bill, special committee report, budget proposal, and communication of parliament.

The work of the RASKE project during the period from 1994 to 1998 has been followed by several projects in

which selected companies have developed and implemented SGML or XML solutions for a specific subset of documents.^[11,12,26] The first implemented document repository in SGML form was the archive of laws and statutes, which was published by the Ministry of Justice in 1997. In parliament, the application of SGML started in 1998, and the Ministry of Finance prepared the budget proposal for 1999 in SGML form. The budget proposal is now created in XML format and the transfer from SGML to XML has started also in the parliament. All of the parliamentary documents are available to all citizens on the Internet free of charge.

THE ANALYSIS PROCESS

The analysis as part of EDM development in an organization, often including more or less formal document standardization, has multiple goals:^[8]

Understanding the domain and the role of documents on the domain. The document management environment may be a complex network of organizations, people, activities, and documents related more or less to each other. The development work is often at least partly outsourced. Understanding the complex domain may be difficult even to people who have worked in the environment for a long time. The technology experts and consultants may be unfamiliar with the domain, the terminology used there, and the ways people work on the domain. The analysis should offer tools for gaining the understanding.

Communication support. The development process may take several years of cooperation by in-house workers in various units of the organization and consultants. The analysis should help to find a common understanding of the domain.

Understanding the needs of the actors. To succeed in document standardization, the requirements of organizational actors as well as person actors should be carefully analyzed and taken into account in the new solutions.

Support the design of document and metadata schemas. EDM development usually includes schema design for documents or for metadata or for both. The document schema design requires knowledge about current document structures and needs for changes. The metadata schema design again requires wide knowledge about the document management practices in the environment and needs for metadata related to content, structure, and context of documents.

Support the redesign of document production. Major development efforts including document standardization often lead to the redesign of the way documents are produced. For being able to implement effective

document processing practices the old practices have to be understood.

Support the specification of requirements for new software systems. The implementation of new solutions often requires new software systems. The document analysis should provide information for specifying the requirements for the software.

Provide documentation for user training. Especially if XML and the structured document approach is adopted, the document authors need understanding of the rules constraining the authoring as well as understanding the needs for the rules. In case of a complex collaborative document production process, each author should also understand his or her role in the whole process. Well written analysis documentation can be used for user training.

A model for the document analysis process is shown in Fig. 2. The circles depict activities, also called *phases*, and the arrows show the control flow specifying the order for starting the activities. The small black circle indicates that all of the following three activities can be started either in parallel or in any order.

The analysis process starts by defining and describing the domain to be analyzed. The domain is an activity whose document management the standardization and improvements will concern. An example of an analysis domain could be creation of the state budget or paper machine manufacturing. Fig. 2 does not explicitly show iteration in the analysis. Once the domain has been defined, any of the subsequent phases may, however, reveal a need to correct or extend previously created models and descriptions. Basically all of the activities may thus proceed to some extent in parallel until the report of the analysis is finished. The domain definition is followed by process modeling, document modeling, and role modeling. Process modeling is used as a means of

Fig. 2 A model for the document analysis process.

identifying smaller activities on the domain, the organizations responsible for them, and the documents created or used in those activities. Document modeling covers the description of document types, their life cycles, their contents, and relationships to each other. In role modeling the most essential document users are identified and their document management activities are described. The user needs analysis studies the needs concerning future document management. At the end of the analysis process, the analysis report is collected and extended on the basis of the descriptions and models produced in earlier phases. The report includes suggestions for future improvements in document management.

DATA-GATHERING METHODS

An extensive amount of data have to be collected during the document analysis phases. The ways in which the data was gathered in the RASKE project can be divided into three categories: project council meetings, literal sources, and interviews.

Project Council Meetings

A council comprising the analysts and representatives from the document support departments of the organizations involved was set up. At council meetings, the work products of the analysis were evaluated and discussed. These discussions were found to be an effective way of gathering information concerning current document management, requirements for the future, and additional data sources.

Literal Sources

The major literal sources can be divided into the following types:

- Reports of earlier projects and working groups in the EDM area. Considerable activity had taken place during the previous year or two. The reports listed a number of problems and needs.
- Printed documents in the analysis domain. Example documents were copied and carefully analyzed.
- Existing written rules and standards concerning documents. Some of the rules were expressed in statutes, some were instructions given by ministries, and some were more informal instructions. For example, there were written instructions for drafting government bills.
- Systems manuals and instructions. Knowledge about current systems is important in identifying the benefits and problems in them.
- General literature describing the domain. In case of legislation, extensive literature is available.

Interviews

The interviews were divided into the following two types:

- Informal interviews with experts in the domain. Interviews were conducted with people working with documents in the organizations. The interviews were supported by charts and other outcomes of the analysis. The domain experts were mostly chosen by the project council.
- Structured user interviews. People using the documents in the domain either within or outside the subject organizations were interviewed to ascertain their requirements concerning document management. The interviews followed structured questionnaires. The goal of the interviews was to obtain more information about the work and tasks done in the user roles and about the needs associated with those roles. The basis for the design of questionnaires was the sense-making theory.^[17] The user needs were connected to situations in the work of the respondents.

MODELING METHODS

The RASKE modeling methods have been chosen from different methodologies and tailored for the purpose of document analysis. XML Schema language and the DTD mechanism have been used as methods for describing detailed document structures. Elm graphs^[27] and similar graphical presentations available in XML schema editors have been used for graphical descriptions of document structures. The most important origins of the other modeling methods were in the object-oriented analysis (OOA) methodology,^[28] in information control nets (ICNs),^[29,30] and in role modeling.^[31] One of the most important requirements for the modeling methods was the clarity of notions and models. Except for the formal XML schemas, the models are primarily intended to support communication and understanding of the area by human readers, only secondarily for computers.

Domain Definition and Process Modeling

The domain definition includes the identification of the activity whose document management the improvements will concern and the identification of the major organizational actors of the activity. Process modeling is used as a means to identify smaller activities, organizations responsible for them, and documents created or used in those activities. Variants of ICNs are suitable for describing relationships between activities, actors, and documents.^[29,30] Basically, ICN models are process models showing a set of *activity* objects, a set of *resource* objects separated into input resources and output resources, mappings indicating the control flow among the activities, and

mappings indicating the information flow. An activity may further be described as an ICN. Figs. 1 and 2 already introduced special variants of ICNs. Fig. 1 showed only one activity circle and but no control flow. Fig. 2 instead showed only the control flow and no resources or information flow. Also, the ICNs used in the domain definition and in the process modeling are special variants of more general ICNs.

Organizational framework

As an ICN, an *organizational framework description* consists of an activity and a set of organizations as input resources. The organizational resources are used in the activity, and their participation can be regarded as an information flow to the activity. Fig. 3 depicts the organizational framework of the domain “creation of the state budget.” In the graphical representation, the broken arrows from the organizations to the activity indicate the information flow. They are labeled by identifiers and associated with phrases briefly describing the tasks of the organizations in the activity. Hierarchic relationships of organizations are indicated by nested rectangles.

It is important in modeling EDM to know the relationships subsisting between the major activities, actors, and documents. The document output model and document input model show the business activities of the domain as a process and the organizational actors of those activities.

The output model shows the documents produced in the course of the activities, and the input model shows the documents used in the activities.

Document output model

A *document output model* consists of a set of activities which are subactivities of the activity of the whole domain, a set of organizations as resources, and a set of document objects as output resources. In the organizational framework model the participating organizations were indicated as sources of information flowing to the domain activity. In the document output model, explicit information flow is shown only to documents. Organizations can be regarded as input and output resources at the same time. While performing their activities, organizations are not only sources of information; those working in the activities increase their experience and expertise and thus the organizations also increase their information resources. This information flow is not explicitly indicated in the document output model, however. In the graphical representation, organizations performing an activity are listed in the upper part of the activity circle.

Fig. 4 shows a document output model for the creation of the state budget. In Fig. 4 the names of the document types produced in the relevant activities are indicated along the broken arrows. The number in parenthesis following budget proposal refers to different versions of the

Fig. 3 Organizational framework for the creation of the state budget.

Fig. 4 Document output model for the creation of the state budget.

same document object. The vertical balk line on the right represents the documentation created during an actual work process. Basically the organizations appearing in a document output model are the same as those in the organizational framework figure. For the sake of simplification, some of the organizations may, however, be left out if their tasks are clear. Others may emerge in the course of process description. For example, in the document output model of Fig. 4, the chancellor of justice and divisions occurring in the organizational framework model of Fig. 3 have been omitted whereas the discussions of

parliamentary groups have been added. The selection of the correct level of abstraction in the process models is important. The purpose is not to describe all the special cases and details.

In the RASKE project, the document output models were found very useful in the user needs interviews in orienting the respondents to the domain. The models were sent to the interviewees before the interviews, and during the interview the respondents were able to comment on the models and indicate their own place in the model.

Document input model

A *document input model* is otherwise similar to the document output model except that instead of showing the documents produced by the activities, it shows the major documents used in the activities. In the processes analyzed in the RASKE project, the repository of the documents used was much larger than the documentation created during the process. In general, the documentation used in an activity by an organization depends on the information needs of the people working in that activity. Document input models are therefore designed after the user needs interviews.

Document Modeling

The document output model shows the document repository created in the domain. Document modeling is used to give more detailed information about a chosen subset of the document types in the repository. Document modeling may also concern new types not appearing in the current repository. Document modeling is divided into three phases:

- Object modeling
- State modeling
- Content modeling

The origins of object modeling and state modeling are in the object-based modeling methodology OOA of Shlaer and Mellor.^[28] Many of the techniques of OOA are also included in the Universal Modeling Language (UML).^[32] In object modeling, document objects are identified and described, and their relationships to each other are described in a *document-relationship diagram* (D-R diagram). The dynamic behavior of a document object over time is described in a state model. In content modeling, the structure of documents is analyzed. In case of the XML adoption, content modeling may include the design of preliminary schemas. Much of the modeling of the three phases takes place in parallel and iteratively. Each of the phases is described below.

Object modeling

In object modeling, a *document object* is an abstraction of a set of documents. An important question to be answered is: What are the real-world documents (or the sets of information) to be modeled as a document object? In the document analysis of standardization projects, the goal is to describe the information in units corresponding as closely as possible to those useful for the organization's performance in future document management systems. In current document management practices, however, the partition of information into documents does not necessarily best support information management.

A short textual description is provided in the object model for each document object class. The document objects and their relationships to each other are described graphically in a D-R diagram, corresponding to the information structure diagram of OOA. Fig. 5 shows the D-R diagram for documents created during the creation of the Finnish state budget. In the example, the standardization covers three documents: budget proposal, finance committee report, and communication of parliament. In the diagram, the document objects of the standardization domain are depicted by white rectangles, the external documents by shadowed rectangles. A one-to-one relationship is depicted by a single arrowhead, a one-to-many relationship by a double arrowhead. A conditional relationship is indicated by the letter C.

State modeling

In state modeling, the dynamic behavior of document objects over time is described by the *state transition diagrams* of OOA. State transitions diagrams of UML can also be used.^[32] A state transition diagram is a behavioral model showing the behavior of a specific document object over time. The activities shown in the diagram change the values of some attributes of the object. Examples of the diagrams can be found in Salminen,^[7] Salminen.^[8]

Content modeling

The main purpose of content modeling is to specify the hierarchic structure of the documents in the development domain. The RASKE content modeling methods are intended especially to support XML schema design. In the first stages of the modeling, the major components of documents in a class are described in a *document component description*. The relationships of the components to the components of documents in other classes are described in a *reuse table*.^[7] The reuse table is intended for analysis of the current reuse of structural components and for showing new possibilities for reuse. A reuse table is defined for each document object. The collection of reuse tables included in the content model is a way of showing the dependencies of different document types.

Most of the modeling in document analysis usually describes the current situation. In the identification of document objects, however, the analysis should be able to anticipate future needs. Grouping information into document objects may differ from current practices and some of the document types may be totally new. Also, detailed content modeling should take into account the requirements for future EDM. The XML offers a formal language with which to define the detailed structure of document content by a schema. XML authoring tools are available for creating and testing the schemas, and also for showing the schema graphically. Elm graphs^[27] were used for graphical descriptions in the RASKE project.

- R1: Budget proposal of a ministry is based on state institution budget proposals
 R2: Budget proposal is created on the basis of budget proposals of ministries
 R3: Finance committee report concerns the budget proposal
 R4: Possible budgetary petitions of parliament members are taken into consideration during the preparation of the budget committee report
 R5: There may be one or more special committee statements included in the finance committee report
 R6: Communication of parliament is created on the basis of the finance committee report
 R7: Communication of parliament is a reply to the budget proposal
 R8: Finance committee report is mentioned in the parliamentary calendar
 R9: Finance committee report is mentioned in the plenary session minutes
 R10: The decisions about the budget, included in the communication of parliament, are mentioned in the decision minutes

Fig. 5 A D-R diagram.

Role Modeling

In role modeling the use of documents by actors is modeled by role objects. A *role object* is an abstraction of the document management needs, tasks, and responsibilities of a group of people. Among existing object-oriented modeling methods, the method of Gottlob et al.^[31] is flexible enough to describe role hierarchies where a user can play different roles at the same time and where roles can evolve. Fig. 6 shows part of the role hierarchy for the document repository created during the creation of the state budget. Role types are depicted by circles. The role types are connected by arrows to the user class, or to the role types whose objects may take on that role. A person as a user of the repository is considered both as an instance of the root type and as an instance of each role type for which that person qualifies. A user in the *organization* role uses documents in the activities of an organization; for example, as a worker in the organization. The use of documents in a *person* role is not necessarily related to any organization. On the other hand, a user may also be in a person role and organization role at the same time. For example, a user may be at the same time be a client of a public library and a citizen needing information preparatory to moving to another country. The double circle around the organization role indicates that a user

may have roles in different organizations at the same time. For example, a person working in the Finnish Parliament as a member of parliament can also be a minister in the Ministry of Finance. During ministerial vacations, a person may take on the role of several ministers at the same time.

With respect to a domain, roles can be divided into internal and external. The users in *internal roles* perform activities in the domain process, whereas the users in *external roles* use documents in some other activities, either in organization roles or as private persons. In the document analysis of companies, all the user roles may be organization roles. Documents created in the public sector are, however, intended for the public and their users may be in a person role not representing an organization in the use situation. Person roles can be classified in different ways; for example, citizen, student, immigrant, senior citizen. The clients of public libraries are typically in person roles while using documents.

Role modeling produces textual descriptions of roles—the way documents are used and the purpose of use. The relationship between document objects and role objects is described in a *document-role relationship table*.^[7] In the table the columns are labeled according to document objects and the rows according to role objects. The letters in the table indicate the type of activity performed by a role object in respect to a document object.

Fig. 6 A part of the role hierarchy for the creation of the state budget.

USER NEEDS ANALYSIS

User needs analysis should cover the document management needs of the individuals and organizations: documents, their use, the systems by which they are used, and the relationships of users. Some of the needs of participating organizations are a starting point for the analysis. More data about the needs of organizations is then collected from literal sources, in the project council meetings, and by the informal domain expert interviews. Needs concerning individuals and groups of persons are part of the needs of the organizations.

Data about the needs of persons are collected by user needs interviews. Structured questionnaires were used in the interviews in the RASKE project. In the questionnaires, data from the following areas were collected:

- Organization and tasks of the organization.
- Personnel tasks in the domain.
- Situations in which documents were used in the domain process and outside the process.
- Documents and information produced and needed in the above situations.
- Systems and databases used in the situations.
- Problems and needs.

The use of documents was associated with specific situations in the work of the respondents on the basis of the sense-making theory.^[17]

The user needs interview analysis produces corrections and extensions to the models created in phases started earlier, especially to the outcomes of role modeling. The analysis of the problems and needs is divided according to the document management components—systems, documents, work processes, and interrelationships between actors. The problems and needs of people in different roles are introduced in the final report, which also includes the above-described models and suggestions for improvements in the different document management activities of the organizations.

CONCLUSION

Nowadays documents are mostly authored using information technology. The use of digital data as information in activities of organizations may, however, be impaired by unintegrated and inconsistent solutions. After storing information in nonstandardized ways, probably for three or four decades, the document management environment of an organization may be

extremely complicated. To improve the utilization of digital media, careful analysis of the environment is needed. The analysis should cover all the components of document management: documents, their users and use, and the business processes in which the documents are used. The information gathered by the analysis provides valuable information about the context and structure of the documents in the environment. In case of using XML, the structural information can be utilized by XML software, for example, in information retrieval. The contextual information, for example, about the business processes where documents are created, should also be provided as accessible metadata to the users. In Lyytikäinen,^[33] we have suggested using the analysis models as contextual metadata and using them as graphical interfaces for information retrieval.

This entry introduced concepts and methods for analyzing documents in their organizational context: A model for the analysis process and methods for data gathering, modeling, and user needs analysis. The methodology was developed and tested in the RASKE project where the goal was to improve the management of Finnish parliamentary documents by standardization. The use of the methods is however not limited to standardization projects. For example, some of the models included in the methodology have been used as a new means to visualize metadata related to European legal documents in Web repositories.^[34] The visualization is intended to help the users of European legal information to cope with the complexity of the legal domain in Europe, and to better locate information from correct sources. Similarly, in other application domains and EDM development efforts, the methods introduced in this entry offer means to describe the complex environment and thereby support for improvements.

ACKNOWLEDGMENTS

The results presented in this entry have evolved during the work of the RASKE project. Mika Hirvonen, Kirsi Heiskanen, Kristiina Huhtanen, Matti Järvenpää, Katri Kauppinen, Antti Lehtinen, Merja Lehtovaara, Virpi Lyytikäinen, Pia Norrila, Reija Nurmeksela, Tero Päiväranta, Pasi Tiitinen, and Maiju Virtanen have contributed as RASKE researchers. The cooperation and extensive knowledge of experts in the Finnish Parliament and government as well as in many other organizations has been extremely valuable. Special thanks are owed to Olli Mustajärvi in the Finnish Parliament for his continuous support and cooperation. The financial support of the Finnish Parliament, Ministry of Foreign Affairs, Ministry of Finance, prime minister's office, Technology Development Center of Finland, and Academy of Finland (under Project 48989) is gratefully acknowledged.

Abstract

The present territory of the republic of Moldova was part of the Principality of Moldavia, currently a province of Romania. This territory was annexed by USSR in 1940 and remained under Soviet dominance until 1991, when the country declared its independence from USSR. The establishment of cultural and educational institutions such as libraries, archives, and museums dates back to the early 1800s. The modest beginnings were followed by a period of development during the interwar period. After the country was annexed by USSR in 1940 and until 1991, when it became independent, the Soviet dominance took its toll on all of these institutions. Restricted access to information and rigid censorship became the norm and libraries, archives, and museums were turned by the communist regime into political propaganda tools aimed at supporting the government ideology. Today, these institutions are undergoing a slow process of modernization by opening their collections to the general public, by refocusing their missions, and by redefining their goals. While government financial support remains scarce, new legislation is being adopted in an attempt to align Moldovan libraries, archives, and museums with international standards.

INTRODUCTION

Moldova occupies the area between Romania to the west and Ukraine to the north, east, and south, bordered by the Dniester and Prut rivers (see Fig. 1). With a population of 4 million, two-thirds of Moldovans are of Romanian descent. Other ethnic groups are of Ukrainian, Russian, and Bulgarian origin. The Romanian and Moldovan languages are almost identical and the two countries share a common cultural tradition,^[1] which became the subject of a severe Sovietization process in the aftermath of World War II.

HISTORICAL BACKGROUND

The eastern part of the Principality of Moldova was annexed to the Russian Empire under the name of Bessarabia following the Russian-Turkish war of 1806–1812. During the period from 1812 to 1918 the political and legal status of Bessarabia underwent several changes: from a provisional autonomy to a Russian province (gubernie). Upon the dissolution of the Russian Empire the first Parliament of Bessarabia, the Country's Council, voted Bessarabia's union with Romania, on March 27, 1918. The interwar period of development and prosperity

for Bessarabia ended on June 28, 1940, when, following the Molotov-Ribbentrop pact, Romania was forced to cede Bessarabia to the USSR. On August 2, 1940, USSR established the Moldavian Soviet Socialist Republic (MSSR), which included a part of the territory of Bessarabia and some districts on the left bank of the Dniester River. During World War II, on July 26, 1941, Romania got Bessarabia back, for a short while. In August 1944, Bessarabia was occupied by the Red Army troops and was again integrated into the USSR.

As a consequence of the perestroika, on August 31, 1989 MSSR's Parliament adopted a law regarding the use of languages in the country's territory. The Romanian language written with the Roman alphabet was declared the official language of the republic. Previously, Russian had been the state language as an attempt of Russification of the majority Romanian population.^[2] During the Soviet period the Romanian language was written with the Cyrillic alphabet.^[3] After the attempted Moscow Putsch Moldova declared its independence from the USSR on August 27, 1991 and in December of that year joined the post-Commonwealth of Independent States along with most of the former Soviet republics. In September 1990, the Parliament of Transnistria (a strip of land between the Dniester River and the Ukraine) unilaterally declared independence from Moldova. Neither Moldova's

Fig. 1 Map of Moldova.

Source: CIA World Factbook. <https://www.cia.gov/library/publications/the-world-factbook/geos/md.html>.

government nor any other UN-member country has recognized Transnistria's independence. Currently, Moldova aspires to join the European Union. To a great extent, Moldova's recent history has been shaped by its having belonged to the Soviet Union which has left a long-standing legacy in regards to the country's social, political, economic, and cultural life. Today's archives, museums, and libraries in Moldova are a reflection of this legacy.

ARCHIVES

Currently, archives activity in the Republic of Moldova is supervised by the State Archives Department (Serviciul de Stat de Arhivă) of the Republic of Moldova. It is the successor of the Archives Section of MSSR's Board of People's Commissioners (Secția Arhivelor a Comisariatului Norodnic) of the Ministry of Internal Affairs (1944–1963) and of the Division of Archives (Direcția Arhivelor) of the Soviet/Council of Ministers of MSSR (1963–1991). Archives activity is governed by the Law Regarding the Archival Collections of the Republic of Moldova (adopted on January 22, 1992 and amended on July 7, 2005), the Regulation of the State Archives Collection (Regulamentul Fondului arhivistic de stat) approved by Government Decision on May 27, 1992, the Regulation of the Public Archives Collection (Regulamentul Fondului arhivistic obștesc), approved by Government Decision on May 30, 1995, and by other legislative and normative acts of more limited coverage.

This legal framework provides for ensuring the conditions of conservation of archival documents and access to them in accordance with international standards. Access to documents is free, once the archives reached repositories at the national level. In general, restrictions on access to documents containing classified information expire after 25 years, restricted access to documents concerning citizens' rights is maintained up to 75 years, and restricted access to marriage records is maintained up to 100 years from the date the document was issued.

Ensuring the physical integrity of documents and access to archival materials in state-controlled archives is difficult due to a series of factors such as: lack of storage space and reading rooms, insufficient equipment, and staff training, under-qualified personnel, inadequate practices that prevent the creation of digital repositories, and most importantly, a lack of managerial strategy and vision at the national level.

The principle of provenance guides all archival activity throughout Moldova. The State Archives Department is responsible for providing centralized record description and inventory. Permanent records are housed by two historic repositories—the National Archives and the Archives of the Social-Political Organizations of the Republic of Moldova—and by specialized central local archives subordinated to national governmental bodies such as the Ministry of Defense, Ministry of Foreign Affairs, Ministry of the Interior, Department of Information and Security, Academy of Sciences, Ministry of Culture, Weather Institute, etc. Intermediary records are preserved in departmental archives or in territorial archives at the municipal and district level. Permanent and intermediary archival institutions oversee the current archives of various institutions, which constitute the source for new records to be transferred to government-level repositories. Guidelines, rules, and regulations

ensure the uniform processing of records beginning with their creation. The *Guidelines to Standard Documents and to Retention Periods for the Public Administration, Institutions, Organizations and Businesses in the Republic of Moldova*^[4] is such a guide, published both in Romanian and Russian.

The National Archives of the Republic of Moldova—NARM (Arhiva Națională a Republicii Moldova) constitutes the country's main historical archives and has its origins in the archives of the Governor of the Bessarabia Region, established in 1815 as the first central provincial archives responsible for gathering and preserving the historical archives of the province.^[5] However, the foundations for theoretical and practical research of historical documents were laid only at the end of the nineteenth century by the Scientific Commission on Archives of the Bessarabia Province,^[6] which was active during the period 1898–1918 and published three volumes of papers. The first historical archives in Chișinău was created within the State Archives only in 1918, after the union of Bessarabia with the Kingdom of Romania. The State Archives in Chișinău were successful in bringing together and organizing collections of historical documents^[7,8] it supported the establishment of the journal *Arhivele Basarbiei* (Bessarabia's Archives) (1929–1938)^[9,10] as well as the publication of several valuable collections of medieval documents.

In 1945, after World War II, the Archives of the Bessarabia Province (most of them moved to Romania during the war and returned to Moldova in 1954) and part of the central archives of the Soviet Socialist Autonomous Republic of Moldova (republic situated on the left bank of the Dniester River during 1924–1940 as part of the Soviet Socialist Republic of Ukraine), most of which were destroyed during the war,^[11,12] were merged and constituted the State Central Historical Archives (Arhiva Istorică Centrală de Stat) of the Socialist Soviet Republic of Moldova and the State Central Archives of the October Revolution and Socialist Construction (Arhiva Centrală de Stat a Revoluției din Octombrie și a Construcției Socialiste) of the Socialist Soviet Republic of Moldova. Those two institutions merged in 1958 to create the State Central Archives of MSSR.^[13] Today's NARM was created in 1990 by joining the collections of the State Central Archives with those of the State Central Archives for Audio-Visual Documents (Arhiva Centrală de Stat pentru Documente Foto-Fono-Cinematografice), established in 1977.^[14,15]

National Archives of the Republic of Moldova preserves all the historical archives (administrative, legal, ecclesiastical, economic, cultural, etc.) of the Bessarabia Province from 1812 to 1944 (except for those transferred to the Odessa Regional Archives,^[16] to Cernăuți in Ukraine, and to some other archives in the USSR, as well as collections still in Romania); all of the archives of MSSR, including the Presidential archives and those of

the Parliament and of the Government; civil records up to 1910 (most of which were microfilmed by the Genealogical Society of Utah); and privately donated materials and collections.

The oldest documents date from the end of the fifteenth century. The volume of paper-based documents amounts to almost one million items. In addition, the photo collection numbers about 150,000 negatives, the audio collection consists of over 5000 magnetic tapes, the movie collection consists of over 15,000 movies, and the insurance companies' records represent about 10 linear meters (33 linear feet) of microfilm. The research library contains about 60,000 books and collections of periodical publications, some very rare, dating mostly from the nineteenth and twentieth centuries. All of the materials have inventories and other finding aids, but most of them are in the Russian language which makes research very difficult for non-Russian speaking scholars. It is only after Moldova's independence in 1991 that finding aids in the Romanian language began to be compiled. Some finding aids have been published in Russian or Romanian.^[17–21] The NARM is situated in a building specifically constructed in 1964 to serve as an archive and it has 13.5 linear km (44,300 linear feet) of storage space.

National Archives of the Republic of Moldova has a branch in the city of Tiraspol, created in 1976, especially for archived materials focusing on institutions in this particular region situated on the left bank of the Dniester River. In 1988, the collections amounted to 696 archival items. The Transdniester secessionist authorities have turned this branch into the Central State Archives of the Moldovan Republic of Transnistria (Arhiva Centrală de Stat a Republicii Moldovenești Nistrene) and it is no longer supervised by the central authorities in Chișinău.^[22]

The Archives of the Social and Political Organizations of the Republic of Moldova (Arhiva Organizațiilor Social Politice ale Republicii Moldova)^[23] ensures the preservation of the public archival contents. It was created in 1991, after the nationalization of the Archives of the Communist Party of MSSR and it preserves, in addition to the archives, various other collections of nongovernmental organizations of the Soviet era and the period after Moldova's independence, such as professional associations, trade unions, etc. This is achieved as a result of bilateral agreements between the Archives and these associations and organizations. The Archives has more than half a million items (about 9 linear km/29,528 linear feet), inventories, and other finding aids in Russian and Romanian. The building, which dates from 1978 was purpose-built as an archive and is considered to be the most successful example in Moldova of a building for the preservation of archival materials.

The specialized central archives subordinated to national government offices or agencies are still being organized and they are undergoing gradual implementation of national archival procedures for conservation and

access. The most frequently used, both by historians and by the general public, are the Archives of the Civil Registry (Arhiva registrelor de stare civilă) which acts as an agency of the Ministry of Information Development (Ministerul Dezvoltării Informaționale). It preserves birth, death, and marriage records for the 1911–1944 period, and more recent records for some territorial and administrative regions which no longer exist.^[24]

Collections of valuable historical documents are to be found in institutions of national significance all over the country, such as the National Library, the Academy of Sciences of Moldova, and many others. The public broadcasting corporation “TeleRadio-Moldova” and the movie studios “Moldova-film” have significant AV archives of historical importance.

Corporate or organizational archives such as those belonging to universities, academies, religious establishments, and NGOs are generally young or very young and contain documents created during their current activity. Their collections, being recent, are not of historical value at the moment.

Territorial archives, including the municipal archives in Chișinău, Tiraspol, and Bălți and the archives of regional administrative divisions (*raioane*), host paper-based documents of the local administrations and businesses from the Soviet era and from the post-1991 period. The preservation of materials in these archives is very inadequate, since their budgets depend on the local administrations.

There are no electronic archives or online finding aids in Moldova. Storage, preservation, and access of digitally born documents are addressed by the Law Regarding Electronic Documents and Digital Signatures (Legea cu privire la documentul electronic și semnătura digitală) adopted on June 15, 2004.

Although, the first article on archival theory in the Romanian language was written by an archivist from Bessarabia,^[25] Moldovan archival science has inherited only the theory, methodology, and managerial practices in place in USSR, some fundamental rules, regulations, and practices in use during the Soviet continue to be in force today. At the same time, during the years after Moldova’s independence, institutional, and personal contacts with Romanian archivists have resumed and knowledge transfer and exchanges of experience have taken place to the benefit of Moldovan archivists. Representatives of Moldovan archives have attended events organized by the International Council on Archives or by archives within the Commonwealth of Independent States, but implementation of their recommendations is not widespread among Moldovan archivists, who are not very familiar with the content of the recommendations. Most Moldovan archivists are francophone and they have participated in several international training sessions on archival practices organized by the French National Archives.

In 1995, the State University of Moldova established a Department of Archival Studies in the Faculty of History, with a group of 10 students per academic year. Four years later the department was shut down. The curriculum followed the model of library education in the Russian Federation and in Romania based on a textbook published locally in 1997.^[26] Many Moldovan archivists received their degrees from the Institute of History and Archival Studies in Moscow or from the School of Archival Studies in Bucharest. This educational system has also been discontinued. Therefore, currently there is no archival education at the graduate level in Moldova. Clerks for secretarial/clerical work in archives are being trained only at the equivalent of an undergraduate level.

There is no professional association for archivists in Moldova. In 1997, the “Paul Gore” Genealogical, Heraldry and Archives Society was established under the patronage of the National Archives of Moldova.^[27] The society organizes various scientific activities such as conferences, symposia, and exhibitions. The society gives the “Ioan Halippa” annual award and every other year the “Paul Gore” award recognizes outstanding research and contributions to the field of genealogy, heraldry, archives, and auxiliary sciences. Another professional association is the Society of Historians-Archivists in Transnistria, established in Tiraspol in 1999.^[28]

In 1998, the periodical *Pergament—Anuarul Arhivelor Republicii Moldova* (Parchment—Yearbook of the Archives of the Republic of Moldova) started being published by the State Department of Archives, the National Archives and Archives of the Social and Political Organizations. This periodical publishes legislation and regulations in the field, finding aids, archival documents, research studies in archives, and auxiliary sciences as well as book reviews.

In 1994, the Republic of Moldova joined the International Council on Archives. Moldova’s archival heritage is under the patronage of the country’s UNESCO National Commission and ICOMOS National Committee.

MUSEUMS

Beginning in 1812, in the aftermath of the Russo-Turkish War, Bessarabia’s development took place in a new historical context imposed by Czarist Russia that did not favor the national assertion of Bessarabians of Romanian origin. This period of Russian domination in Bessarabia’s czarist history offered few opportunities for the development of the national culture but illustrates a great need for training models. It is significant because of the efforts of the society to search for methods of safeguarding and preserving the province’s cultural heritage (mainly of archaeological and historical vestiges) and establishing a positive attitude towards the past and its legacy.

The awareness of preserving cultural assets had existed in Bessarabia's society over several centuries and during the early nineteenth century it resulted in the creation of major collections of archeology, history, and antiquities and in the organization of various exhibitions of agricultural, industrial, ethnographic, and art objects. The first public museum was the Zoological, Agricultural, and Crafts Museum, established in 1889 as a result of the Exhibition of Agriculture and Industry which took place the same year in Chişinău. The mission of the museum was twofold: "scientific and practical, to contribute to the development of natural sciences, and to increase the farmers' awareness about the latest developments in the field of agriculture."^[29]

Between 1903 and 1905 the museum building was erected in Moorish style, and it was inaugurated on April 30, 1906. Member of all social classes enjoyed the exhibits that highlighted their culture by displaying different kinds of artifacts related to several disciplines such as ethnography, archaeology, history, and numismatics. Donations had a decisive role in developing the museum collections until 1918. The education of the general public was seen as the museum's primary responsibility. The museum was made available to the public under a program that provided access "to local residents from 11 A.M. to 2 P.M. on Sundays, and to those visiting from other places and to groups any day at any time."^[30] Until 1918, the museum was visited annually by about 25,000 visitors.^[31] The second museum in Bessarabia was the Museum of Agricultural and Natural Sciences opened on November 1, 1914 in Tighina (Bender). This first group of museums of natural sciences and ethnography fostered scientific research in these particular fields and boosted the development of a core group of a local scientific elite.

The nineteenth century is known in European museum studies as the century of national museums. Due to the vicissitudes of history, Romanians in Bessarabia could not showcase their history in national museums. However, during the mid-nineteenth century there was a general increase in interest in the country's past and history, which generated interest in collecting and establishing various cultural associations and scientific societies focused on studying the nation and its past through documents and monuments of historical significance. The activity of the members of the Scientific Commission of Bessarabia's Archives (Comisia Ştiinţifică a Arhivelor din Basarabia), of the Historical-Archaeological Religious Society of Bessarabia (Societatea Istoric-Arheologică Bisericească din Basarabia), of the Society for Research of the Dniester Region (Societatea de Cercetare a Ținutului Nistean) resulted in the emergence of the concept and design of a museum of archeology.

Despite the fact that these ideas were not implemented, because of the antinationalist policy promoted by the Russian government, they represent an important step in development of attitudes regarding museums. They show

an interest in such institutions, as evidence of the awareness of the need to preserve antiquities and to create a national museum of history. Russian czarism could not allow the establishment of national museums in the subordinated provinces. But taking into account the development of museum studies, the development of history as science, and the spiritual needs of the society, czarism imposed a unique concept for history museums highlighting the history of the church (or "church museums").

The establishment of the Church Museum (Muzeul bisericesc) in 1906 in Chişinău is directly connected to the activity of the Historical-Archaeological Religious Society of Bessarabia, founded in 1904. According to its bylaws the mission of the Society was "to collect written documents with religious character, church books, icons, objects of worship; to research archeological and religious materials kept in various state institutions and private collections; in order to create a museum aimed at preserving church antiquities."^[32]

This museum remained active until 1940. The creation of the Church Museum meant "a very clear manifestation of the Bessarabians' religious memory. Through this museum the religious thinking and church life continued to preserve their identity in Bessarabia's space within the context of the Russian Empire's imposing uniform religious activities."^[33]

The emergence of public museums is one of the most important events in Bessarabia's cultural life during the mid-nineteenth century. Museums were seen as an important factor in the development of national consciousness. They were necessary to preserve traditional values in a society threatened with losing its historical memory. During this period, museums managed to occupy a particular place in social consciousness, the same place as other institutions that preserve human memory such as archives and libraries. Nonetheless, public museums of this period only partially reflected the national culture and society and could not meet the national aspirations of the local population.

Bessarabian museums of the early twentieth century followed the managerial and organization principles of the late nineteenth century Russian museums intermingled with the individual character and structure of their own collections. Until 1918, the development of museums in Bessarabia was mostly of a spontaneous nature, as a reaction against all kinds of factors aimed at cleansing the Romanian population's national identity by the Russian authorities. There was no specific body to coordinate museum activity, the government's role being solely that of recording the existence of such institutions. Museum activity largely relied on private initiative. Prior to World War I there was no specific legislation targeting museum operations.

After the 1918, the unification and the creation of a unitary Romanian state (as a result of which Bessarabia joined Romania), the new Romanian government adopted

several pieces of legislation regarding the development of museums in Greater Romania. In April 1932, the Law for the organization of public museums and libraries was adopted, representing the main legislative act that governed the development of these institutions during the interwar period. According to this law, the government became the sole body invested with control over all museums and charged with ensuring the integrity of Romania's museum patrimony. The law defined the scope of the "cultural goods" concept, museums' goals, objectives and their mission and also stipulated the establishment of a Council of Museums, which was to approve the creation and/or closing of museums, to coordinate their activities and operations. Through this law all museums received the status of scientific research institutions. The Zoological, Agricultural and Crafts Museum in Chișinău became the National Museum of Natural History and it was to act as "an institution of scientific research in which all disciplines dealing with natural science were to find their place."^[34] In 1926, the first issue of the museum's journal was published: *Buletinul Muzeului Național de Istorie Naturală din Chișinău* (Bulletin of the National Museum of Natural History in Chișinău). According to Decree-Law No. 3783 of November 1937 the National Museum of Natural History in Chișinău became Bessarabia's Regional Museum (Muzeul Regional al Basarabiei), with the mission "to gather and study materials documenting Bessarabia from the standpoint of its natural sciences, anthropology, and history. The museum was to become an institute of rigorous scientific research at the regional level and also a central archives and collections repository."^[35]

During this period museum scientists engaged in research in the field of natural sciences, conducted archeological digs, and participated in ethnographic explorations which contributed to increasing the museum's holdings. During the interwar period, as during the previous period, Bessarabia's Regional Museum continued to remain the most prominent museum in Bessarabia. During the 1918–1940 period, new museums were established such as: The Antiquities Museum of Cetatea Albă (1919), which published its own journal, *Buletinul Muzeului Cetății Albe*; the Fine Arts Museum in Chișinău (1939), two museums of history of religions in Ismail and Bălți, and the Economic Museum in Bender.

After 1944, when Moldova was incorporated into the USSR, museum history entered a new stage which changed not only the role and significance of museums, and the principles of museum organization and activity but also the concept of museum per se, i.e., the essence of museums as institutions. During the communist period a new approach to museums was implemented: museums were turned into political schools of mass education and indoctrination, they became part of the communist ideological machine. They acquired political-cultural attributes. This process became manifest mostly through the creation

of new institutions such as "historical-revolutionary" museums, memorial museums, and antireligious museums.

For many decades, the main method in guiding exhibition activities in museums was the organization of thematic exhibitions while the main criterion for assessing museum activities was the ideological content of the activities they organized. Museums were expected to reflect in their exhibits the achievements of the socialist construction and the superiority of communist lifestyle. In spite of this requirement, museums did not have in their collections items specific to Soviet efforts, which started only in 1917. Therefore, museum objects removed from exhibits were replaced by enlarged texts and slogans, symbols of the communist doctrine.

A new phenomenon in Moldovan museum history was the establishment of antireligious museums, museums of "scientific atheism," in which atheism became a state religion, one of the main components of the communist state ideology. In addition to promoting "scientific atheism," in their instructional and educational activities, museums were required to reflect events of political importance in the nation's life: congresses of the Communist Party, elections of the Supreme Council of the USSR, various V.I. Lenin jubilees, anniversaries of the October Revolution, commemoration of significant events in the history of the USSR, etc. Museums were designed as political stages for socialist events, as powerful weapons of political education, and as a means for illustration and dissemination of the communist doctrine. Despite the museums' efforts to escape the ideological constraints, they remained ideological institutions forced to abide by the communist party's directives, turned into Marxist-Leninist propaganda tools.

Beginning in 1944, when Moldova was incorporated into the Soviet Union, museum activity was coordinated by MSSR's Board of People's Commissioners. In 1946, the institution was called the Council of Ministers of MSSR. In 1953, the Ministry of Culture of MSSR was created, and museums were placed under its jurisdiction. This system of coordination of museum activities remained in place without major changes until 1991. The ideological and propagandistic aspect of museum activities remained the major mission of museums throughout the Soviet regime. According to the communist ideology "museum should occupy a prominent place in promoting the Communist Party policy, thus contributing to building the Marxist-Leninist consciousness and ensuring the quick transition from communism to socialism."^[36]

During the Soviet regime the Moldovan museum scene was marked by the emergence of a new category of institutions: "museums of the birthplace region" (muzeul ținutului natal), featuring collections of local history, natural sciences, ethnography, and art. The name of this kind of museum kept changing during the Soviet period: in 1940 it was called the Republic Museum for the Study of the MSSR Region (Muzeul Republican de Studiere a Ținutului al RSSM), in 1957 it was called the State

Museum of History and Study of the Birthplace of MSSR (Muzeul de Stat de Istorie Și Studiere a Ținutului al RSSM), in 1983 its name changed to the State Museum for the Study of the Birthplace of MSSR (Muzeul de Stat de Studiere a Ținutului al RSSM). This period was characterized by a significant growth of the number of museums. In 1985, their number amounted to 83.^[37]

This period is also significant for the emergence and development of memorial museums, aimed at featuring cultural and political personalities of particular importance in Russia's and the Soviet Union's history and culture while such important personalities at the local level were completely ignored. Leaders of the national cultural, artistic, political movement, or figures that opposed the communist regime were ousted and their contributions to society were completely neglected. A museum network was established nationwide, but there was no variety in their profiles and collections. The Soviet totalitarian system imposed from top down a common vision, a similar museum display regardless of the museum's profile, aimed at highlighting Russia's progressive role in people's life, and at featuring the achievements of the Soviet republics to the well-being of the masses throughout the USSR.

This led to a distortion of national history and culture. During the Soviet regime RSSM, as a simple administrative-territorial subdivision of the USSR, did not have her individual history and therefore there was no museum of national history. During this period, there was a unique history—that of the USSR—that identified itself with the history of Russia. Museums were perceived by public consciousness as agencies of communist propaganda. Particular attention was paid to promote revolutionary ideas. The number of history and revolutionary museums increased through the 1980s and they remained the most important category of museums every Soviet republic had to have. During this period there was no specific museum legislation since everything was coordinated by the omnipotent communist party.

Moldova's independence and sovereignty in 1991 has produced radical changes on the social, economic, and cultural arena. The process of democratization of institutions included museums as well. A characteristic feature of the development of museums after 1991, during the transitional period was to reduce their number. The national revival of Bessarabian Romanians, the democratization of public life, and the new social and political conditions all dictated the closure of political museums and memorial museums devoted to Soviet heroes. At the same time there was a drastic decline in museum visitors. Today there are 70 museums in Moldova, with three national museums: the National Museum of Ethnography and Natural History (originally opened in 1889), the National Art Museum (1939), and the National Museum of Archaeology and History (1983). These are also state museums, as well as local or institutional museums. In December 2002, the Museum Law was approved.

The national association of museographers is called Museion. In 1998, the National Museum of Ethnography and Natural History participated in a European competition—the European Museum Forum—where it received an award. Since 1995, the State University of Moldova, Faculty of History and Psychology, Department of Museum Studies, has prepared specialists for museums. There is a specialized museum journal, and since 1992, two museums have published their own journals: the National Museum of Archaeology and History of Moldova has published *Tyragetia* and the National Museum of Ethnography and Natural History has published the *Buletinul Muzeului*, both journals containing a section for Museum Studies. Since 2005, two museums—the National Museum of Archaeology and History and the National Museum of Ethnography and Natural History have a dual subordination: the Ministry of Culture and Tourism and the Academy of Sciences. Currently, museum activity is focused on researching and establishing a national museum patrimony, on reintegrating in the local circuit the national history and cultural values to reflect the nation's identity and to educate future generations of visitors. Along with the depoliticization of Moldovan museums this will represent radical changes in the development of museums and museum studies in the country.

LIBRARIES

The first public library was established in Chișinău in 1832, as a result of an act issued by the Russian Empire. It began as a very modest private collection of 428 volumes. Bessarabia's civil governor asked neighboring Romania for support to increase the library's holdings, but rigid censorship rules imposed by the czarist regime allowed only 36 volumes to cross the border to be added to the library's collection.^[38] For more than a century, the library was moved from one building to another and during the interwar period it occupied several rooms in the City Hall. In 1944, the Central Library of the Moldovan Soviet Socialist Republic was created through the merger of this first public library in Chișinău and the Central Library in Tiraspol.^[39,40] In 1961, the library moved into a purpose-built construction where it has continued to operate as the National Library of the Republic of Moldova (NLRM). In 1986, NLRM acquired a second locale in its immediate vicinity, the building of the former Theological Seminary which today hosts the fine arts and the multimedia collection.

In 2007, Moldova reported a total of 2931 libraries: 1383 public libraries (including NLRM and the National Library for Children), 1453 school libraries, 21 college libraries, 16 academic libraries, 27 medical libraries, 8 agricultural libraries, 20 technical libraries, the Library of the Science Academy, the Parliament Library, the Office for Intellectual Property Library, one trade

union library, and one library for the blind. In 2007, a total of 3,148,000 new items were added to these libraries' collections, out of which 1,457,000 (46.28%) were in Romanian, the country's official language. More than 87% of the libraries are in rural areas.

Statistics indicate that in 2007 there was a total of 1,952,080 active library users, of which 853,400 are under 16 years of age.^[41] This shows that almost half of the country's population uses libraries despite the dated collections, and even though most of the books are still in Russian and despite the traditional library services often reduced to provision of reading space in old reading rooms. Though the financing of libraries is insufficient and their book stacks are replenished slowly, the number of visits is constantly growing. More than 10 million (10.2 million) people visited libraries in 2005, 3% more than in 2004.^[42] Moldova has a very high literacy rate of 96%.

National Library of the Republic of Moldova is the premier library of the country, directly subordinated to the Ministry of Culture and Tourism.^[43] National Library of the Republic of Moldova coordinates the project of a shared cataloging system, SIBIMOL, jointly funded by the Ministry of Culture and Tourism and the Soros Foundation for an Open Society, aimed at automating library operations and services by establishing local and interregional networks with shared catalogs, linking them to the NLRM's central catalog, and later making them accessible via the Internet. As of January 2006, NLRM's online catalog contained records for over 140,000 books, 7500 serials, and 21,500 articles from Moldovan periodicals, as well as 1600 AV materials. As of January 1, 2007, NLRM's collections amounted to 2,510,254 items (2,160,941 books and periodicals, 25,624 AV materials, 136,484 graphic documents, 61,142 music scores, 214 manuscripts, and 1885 e-documents). In 2006, NLRM reported 11,654 active users who borrowed 588,720 documents.^[44]

Under the Library Law, seven copies of every national publication are to be deposited with the National Library, which then distributes them to other libraries. A "Legal Deposit" department was set up in 1999 to supervise this system and make it work better. In fact, because of the recession, publishers are not honoring their legal obligation, and are depositing 1–4 copies, if any. This makes it impossible to keep a full collection of all the books published in Moldova, and to collect the data needed for the books-in-print catalog. National Library of the Republic of Moldova makes a serious effort to promote its collection and new acquisitions through a series of events: the annual National Book Fair, musical and arts events, literary meetings, lectures, exhibitions, etc. It also does research in a number of fields (history of books, etc.), organizes colloquia and symposia, and produces numerous bibliographies and publications on library science, such as the *National Bibliography (Exteriorica)*, *Culture in Moldova*, *The National Calendar*, and *The Bibliological*

Bulletin. In 1992, NLRM began issuing the quarterly *Magazin Bibliologic* which is distributed to libraries throughout the country to support all librarians' continuing education.

The National Library for Children (NLC) was established in 1944 with an initial collection of 10,000 volumes. Today its collections amount to 260,000 items, including audio-visual materials. Forty-seven percent of its collections are in the Romanian language. The library reports 12,000 users per year.^[45] In 1997, NLC became a member of the International Board on Books for Young People.^[46] The library has earned a national reputation by organizing the annual Children's International Book Fair.^[47]

The Chişinău Municipal Library (CML) is one of the largest and most dynamic in Moldova. It was established in 1877 with a collection of 8073 volumes. By 1932, its collections consisted of 110,000 volumes, 93,800 of them in Russian. In 1941, the library was destroyed by fire. In 1944, it was reestablished by the Soviet authorities under the name of Central City Library. In 1991, it became the Chişinău Municipal Library.^[48] Currently, its collections amount to one million volumes. Every year 150,000 patrons use the library's 31 reading rooms. In addition to print materials, CML offers access to electronic books and online databases. One of the branches of CML is a special library, The Public Law Library, situated in a downtown remodeled building equipped with state-of-the-art technology that allows access to legal databases including LexisNexis.^[49] Chişinău Municipal Library issues several periodical publications among which is the monthly *Bibliopolis*.

Among special libraries, the Scientific Medical Library (SML) has engaged in a partnership with the North Carolina South East Area Health Education Center. Scientific Medical Library serves as the library of the State Medical and Pharmaceutical University of Moldova. It also acts as the National Medical Library of Moldova. The library collections contain 1,200,000 books, almost all in Russian and very dated. International statistics situate Moldova in the last place in Europe in terms of library expenditures per capita. Unlike Denmark where the governments spends 64.27 Euros per person, in Moldova library expenditures amount to 0.35 Euros (about half a dollar).^[50] In 2006, the partnership brought to SML 10,000 medical books and periodicals in English. In addition, the program provided free access to four medical databases.^[51] Other special libraries include the Library of the Parliament, established in 1978, with a collection of 11,400 books and 112 periodical titles. The Science and Technology Library was established in 1969 in Chişinău. In 2003, the library reported a collection of 13.5 million volumes.^[52] The Library of the Academy of Economic Sciences was established in 1991. It currently holds 330,000 volumes and provides access to online resources. It serves as repository of publications issued by the International Bank for Reconstruction and Development.^[53]

The Library of the State University of Moldova, established in 1946, is one of the largest government-sponsored academic libraries, with two million volumes. The Library of the Alecu Russo State University in Bălți is the only academic library in Moldova that operates in a purpose-built building. The library harbors more than 1 million items and it is the most modern government-funded academic library in Moldova, providing access to electronic databases and e-books. The library also serves as a regional repository for publications issued by the World Bank. Among private universities, the Free International University of Moldova, situated in Chișinău, is the most prominent. Established in 2002 along with the university, the library provides remote access to electronic resources and virtual reference, organizes conferences, publishes conference proceedings and is strongly engaged in the implementation of modern information technologies.

Moldovan library collections are dated and mostly in Russian.^[54] Most new books have been donated. Romania has been a major donor. Several public libraries in Romania have developed a sister library program through which they have endowed Moldovan public libraries with Romanian books. Under its Library Support Program and in cooperation with various international organizations, the Soros Foundation has funded a series of programs to support the acquisition of various books and publications: foreign books, subscriptions to international journals, participation in the Pushkin Project. Agencies run by other countries fund the acquisition of foreign publications only. The Alliance Française, for example, contributed books in 1999, under its "100,000 Books for Moldova" program. In the same way, the German Embassy has opened a German-language reading room at CML. The Soros Foundation Moldova supported school libraries with reference materials that helped establish resource centers in elementary and high schools nationwide. In October 1997, librarians in resource centers from the 18 schools attended a 2 day seminar with the motto "Books and Information for Education." The issues covered concerned the role of the school library in school life, the value of reading and its importance for students, use of international standards in library activity, and document classification.^[55]

Penetration of the new information technologies into Moldovan libraries is very slow. Because of the country's economic situation, the 1994 Library Law and the Library Support Program, launched in 1998, have done little to improve the financial situation or technical infrastructure of libraries, despite the claim for modernization and vision for the future.^[56] Currently, there are 1653 computers for library staff in the entire library system in Moldova (an average of 1.77 computers per library) and only 1126 are connected to the Internet. There are 892 public terminals out of which 737 have Internet connections. Most of these public stations are to be found in academic libraries: 417 computers, 380 with Internet connection.^[41] It is also mostly the academic library sector that provides access to

foreign databases purchased through a multicountry consortial system, supported by Electronic Information for Libraries (eIFL.net), a nonprofit organization that advocates for the wide availability of electronic resources by library users in transitional and developing countries. The eIFL Direct Moldova consortium comprises 16 major libraries: 10 academic, 3 public, and 3 special libraries.^[57]

The National Book Chamber (NBC) was established in 1957 and is responsible for compiling the National Bibliography (books and periodicals, analytical bibliography) and keeping the ISBN and ISSN distribution records. Set up under the Soviets, the Chamber was linked directly to the government through the Publishing Activities Committee, to which it was answerable. Today, it reports to the Ministry of Culture and Tourism. In 2007, NBC celebrated 50 years of existence. An entire issue of *Magazin Bibliologic*^[58] was dedicated to this event. A monograph also highlights the institution's achievements during this period.^[59]

Librarians of all kinds belong to the Library Association of the Republic of Moldova (LARM), established in 1992 and a member of IFLA (International Federation of Library Associations and Institutions) member since 1994. Occasionally LARM representatives attend international library meetings, book fairs, etc.

Library science education began in 1960 at the State University of Moldova, Department of Library Science, Information Assistance and Archival Studies which offers undergraduate and graduate degrees.^[60] Some 25 students graduate every year but after graduation not all of them choose to work in libraries or archives because of the low pay. Librarians also attend professional development courses provided by the Center for Continuing Education in Librarianship, established in 2001 with funding from the Soros Foundation's Training Program. The Center was funded for 3 years and currently is diminishing its activity for lack of financial reasons. The Soros Foundation also covered courses and grants for librarians at specialized institutions abroad and attendance of international conferences. Moldova's Library Law adopted in 1994, with amendments in 2001, 2003, and 2005,^[61] specifies the legal status of libraries and includes detailed provisions on library collections within the context of automation of services and digitization of documents. The Library Law also stipulates the role and activity of the National Library Council, that acts as an advisory board on library issues to the Ministry of Culture and Tourism.

Moldova's cultural policy priorities were outlined in the national program "Development and Protection of Culture and the Arts in the Republic of Moldova, 1997–1998," extended to 2000–2005. In November 2005, the *Program on the government's activities for 2005–2009*, named "Modernization of the country — welfare of the people," was initiated, followed by the *Program on the development of the regions, 2005–2015* entitled "Moldovan Village." These programs include a variety of

objectives targeting the cultural and educational field such as: the protection of the local cultural heritage; the restoration, and development of the regional houses of culture, libraries, and museums, and “e-culture” that introduce the new forms of promoting culture through electronic media in different sectors of the national culture. In order to implement some provisions of these programs, in 2006 the Ministry of Culture and Tourism elaborated the drafts of several important normative documents and laws: a draft of the Strategy on the Development of a National System of Libraries.^[62] It is still to be approved.

In addition to writing long-term programmatic documents, Moldova’s policy makers need to substantially support the cultural and educational sector, to contribute to the development of the infrastructure that would facilitate a faster penetration of the new information and communication technologies that would bring progress in every citizen’s daily life. The Moldovan information society is still to come.

Moving Image Indexing

James M. Turner

School of Library and Information Sciences, University of Montreal, Montreal, Quebec, Canada

Abstract

Several types of moving images are available now, and each has its own indexing needs. In addition, a number of levels of indexing are necessary, depending on the type of image, the type of collection, and the needs of users. In information science, work on providing indexing to the various levels has largely to do with finding ways to recycle text created for other purposes in the processes of production, in order to point to individual shots, sequences, scenes, or chapters. Such text recycling needs to happen automatically, through the application of algorithms developed for this purpose, since indexing at the various levels by humans is prohibitively expensive in most circumstances. Multilingual indexing is an issue in the context of retrieving images in a networked environment. Another issue is access to moving images using indexing approaches other than subject indexing. Tagging of images by users is prevalent in the networked environment, and a discussion of its usefulness is included. Finally, there is some speculation on what the future of moving image indexing might bring.

INTRODUCTION

The term “moving images” is actually a misnomer, since moving images are actually still images that give the illusion of movement when they are displayed in rapid order. For 35 mm film, such as that projected in movie theaters, the rate is 24 images/sec, and for video, the rate is 30 images/sec (the video frame rate actually varies considerably, depending on various technologies and standards). Early attempts at making moving images resulted in a number of intriguing technologies and gadgets such as the thaumatrope, phenakistiscope, zoetrope, praxinoscope, and so on, and today people still enjoy the simple magic of flip books, kaleidoscopes, and animated gifs, along with moving images made using highly sophisticated digital technologies. The first public projection of moving images on film took place in France in 1895. Now, over a 100 years later, many technologies for making moving images are available. Home video cameras are practically a household staple, and even young children learn not only to use them but also to edit their work on computers using software that is easier to use than a word processor.

Large collections of moving images have built up in local, national, and international institutions and in the homes of private collectors. Compared to methods for providing access to books and other text materials, methods for providing access to moving images remain relatively undeveloped. Historically, the landscape of collections of still images, moving images, and sound has been characterized by ad hoc organization. This began with museum collections of paintings, prints, and drawings, and continued through the building of collections of

photographs in libraries and archives, and later with moving image and sound collections in studios, libraries, and archives of all types.

Since most formal information was historically consigned to books, all other types of materials came to be considered as special collections, and emphasis was placed on developing cataloging and classification systems for organizing printed materials. Those responsible for the management of audiovisual collections of all types were left to develop their own methods for organization of these collections. For collections of art images, the methods developed by managers of such large and important collections as those at Harvard and Princeton came to be borrowed elsewhere, but essentially, each collection was organized in isolation, its methods based on practical issues and with specific goals in mind, usually to support scholarship in art history.

With some exceptions such as cinémathèques, national broadcasters in some countries, the UCLA Film and Television Archive, and the National Audiovisual Institute (Institut national de l'audiovisuel, INA) in France, moving image collections still suffer from levels of organization insufficient to serve useful purposes. In the studios, very little organization occurred until a pressing need developed. The same is true of the television networks, where emphasis has always been placed on the present and the future. With time and the development of technologies not even dreamed of when the production of movies and television programs began, owners of large collections of audiovisual works are coming to realize the importance of archival materials as heritage materials, cultural witnesses, and for their important commercial value.

Perhaps the main force driving the progress now rapidly being made in developing methods of organization in recent years has been the arrival of the World Wide Web. The possibilities of networking collections, providing remote access to them, broadening the use of collections, exchanging metadata, and serving a much broader user base are very great. Such possibilities were early recognized in the information science community, and a great deal of work has already been accomplished in addressing the new issues arising from the existence of the Web. Along with this, increased awareness of the immense complexity of developing and coordinating standards of all types, providing for interoperability, access to very large masses of documentation, and preserving digital materials has taught us that a great deal more work needs to be done if we are to achieve the performance levels we so desire from networked systems.

In this entry we focus on issues in indexing moving images so that users with a broad variety of needs can find them. Providing remote access to collections greatly increases the number of potential users. More importantly, it creates new possibilities for using materials. Indexing used to be targeted to specific groups of users. However, in the new environment, the managers of collections cannot even know who will come and use their collections if they provide access to the broad internet community. We discuss the various levels of access, the relationship between text and image, multilingual indexing, indexing other than subject indexing, image tagging, and look briefly at the future of moving image indexing.

LEVELS OF ACCESS

Interestingly, if problematically, there is no consensus on the terminology used for these levels of access in the literature of moving image management. This literature includes the areas of information science, computer science, film studies, literature, popular culture, and cultural studies. The most widely used general term for managing moving image collections is “asset management,” a vague, unfortunate term suggesting financial or banking activity and reflecting the preoccupation of the commercial movie studios. However, since it is now deeply implanted, there is no point in trying to control its use. Section, chapter, sequence, scene, and shot are used diversely in various contexts, with meanings sometimes overlapping or outright jumbled. Thus in discussing these issues it is useful, at least until the terminology becomes stable, for authors and others to define clearly what they mean. Various kinds of users need various levels of access to moving images. This needs to be taken into account in building information systems and in providing indexing to their content. Here we discuss levels of access from the point of view of information organization for providing access to users of collections of audiovisual materials.

The notions of *ofness* and *aboutness*, propounded in seminal articles on the subject of picture indexing by Sara Shatford^[1,2] and Karen Markey,^[3,4] arise from work by the art historian Erwin Panofsky in the area of interpretation of works of art. Panofsky^[5] describes three levels of interpretation of images, which he calls pre-iconographic, iconographic, and iconologic. The first level (pre-iconographic) refers to primary or natural subject matter, requiring familiarity with objects and events for interpretation. The second level (iconographic) refers to secondary or conventional subject matter, requiring familiarity with specific themes and concepts for interpretation. The third level (iconologic) refers to tertiary or symbolic subject matter, the meaning of which is derived from complex manipulations impossible to elaborate completely. The levels described by Panofsky have been widely adapted to picture indexing, although the process of interpretation involves a number of inconsistencies. Since the practice applies mainly to art images, we will not discuss it further here. However, it illustrates the notion of levels of access, a concept very much present in indexing moving images.

The levels of access range from whole productions such as movies, through various divisions of such documents, down to individual images or frames from them. A helpful way to contextualize the levels is to define them using the *Rules for Archival Description* (RAD),^[6] useful for describing materials down to the item level. For moving images, additional levels need to be added to reflect the granularity required to index moving images in some contexts:

<i>RAD levels:</i>	Fonds
	Series
	Subseries
	File
	Item
<i>Additional levels:</i>	Chapter
	Scene
	Sequence
	Shot
	Frame

In between the most general level of indexing (in the case of movies, generally the Item level in the RAD hierarchy, although in some cases this could be the series or subseries level) and indexing individual frames, movies can be divided at a number of levels: there are the main divisions such as the “chapters” found on commercial DVDs; each chapter is composed of a number of sequences or scenes, these in turn composed of shots, made up of individual frames. Videos and television programs can have similar divisions, or different divisions, depending on the nature of each work. In the case of television programs, a situation comedy, for example, can be divided by season, episode, and thence as a movie, with sequences, shots, and frames. In contrast, a current events program might have

an introduction, a kind of table of contents (roster of what the individual segments will be), the segments themselves, each an individual production, and some concluding material, along with previews of the next week's show.

The level at which a collection needs to be indexed depends on its users and the type of material it holds. For collections that include films along with other types of materials, the most general level is likely what is needed. A research collection will want to offer more detailed information, both in the cataloging and the indexing. A television archive needs tight control over specific information about the production issues. In some cases, individual shots, even individual frames, need to be indexed.

Item-Level Indexing

At the highest, most general level, moving images can be treated as if they were books, for example, in the collection of a public library that offers DVDs of movies to its users. Methods for organizing collections at this level are available through chapters created for this purpose in the *Anglo-American Cataloguing Rules* (AACR2R), presently being replaced by the development of the *Resource Description and Access*^[7] rules. Other tools such as Yee's^[8] work on moving image cataloging, the *Compendium of cataloging practice for moving image materials*,^[9] and the revision of *Archival Moving Image Materials: A Cataloging Manual*^[10] offer methods targeted more specifically to moving image collections. These offer rules for providing access points such as author (director), title, the principal players, and so on.

In mixed collections, it is arguably more useful to provide subject access via the same controlled vocabulary that is used for other types of materials such as books. At this level of indexing, this is often perfectly adequate. However, in collections that house only moving images, many in-house controlled and uncontrolled vocabularies can be found. The work of harmonizing these in a networked environment is best accomplished by adopting metadata standards that will foster interoperability. The Association of Moving Image Archivists (AMIA),^[11] one of the most important players in the movement to better organize moving image collections jointly with the Library of Congress, is building a union catalog to offer access to moving image collections worldwide. This service is called Moving Image Collections (MIC)^[12] and offers portals notably for cataloging and metadata resources and for preservation resources.

Chapter-, Scene-, and Sequence-Level Indexing

At present, these ever-finer levels are mainly found in a production context, notably for finding existing materials to be recycled in new productions. If access at these levels were made more universally available, the systems would of course find new users, because they would permit levels

of analysis, comparison, and synthesis of content that are not readily available now. Since the names of chapters are already defined in the context of commercial DVDs, they can be readily included in cataloging records to provide a kind of table of contents for users.

Within each chapter, however, analysis of the scenes, and within these the sequences, are not so readily provided. As we noted, there is not even consensus on the terminology for these divisions. What some call a "scene," for example, is called a "sequence" or even a "shot" by others. Still, a great deal of work is going on in computer science to detect divisions automatically. In general, this works well for shots, although certain types of images confuse the detection algorithm, such as explosions, during which the image content from frame to frame is so different. At the other extreme are cross-fades, in which one scene so slowly becomes another as to fool the algorithm into thinking the scene is continuous. Such problems are relatively minor, however, and with time more sophisticated algorithms will take them into account and a perfect score will be achieved.

Scene and sequence detection are not so simple, however, since they are logical divisions with no easy cues for algorithms that work on the pixels in the image to detect. However, at least with scripted productions, we can imagine algorithms that make use of the script, coding used by editors, and other such documentation, to identify automatically and accurately where there is a scene or sequence change. For the moment, however, human indexers must do this work.

Shot-Level Indexing

Shot-level indexing or shot-by-shot indexing provides a level of access that is very useful in a number of situations. It can be vaguely compared to back-of-the-book indexing, in that users could identify a concept, object, event, or person they wanted to see, look it up in the index, and be led to images of it. If shot-level indexing were available, filmmakers, researchers, film and other historians, students, even the general public would all be able to make good use of it. However, all indexing by humans is expensive and time consuming, so shot-by-shot indexing is carried out at present only if there is a payoff that can justify the cost at the other end, or if it is absolutely necessary in order for users of a collection to be able to do their work. At present there are two principal cases of this, and each has its own needs: stockshot libraries and television newsrooms.

Stockshot libraries are built by recycling material (called outtakes) that was shot for some purpose but never used in the final product. They can be the rejected takes of a shot that did get used, shots the editor simply decided not to use in the final cut, even sometimes material that is shot for stock because a cameraperson on location noticed something nearby that was not part of the shoot, but that

he or she felt would be useful material for the stockshot library. Interestingly, in stockshot libraries the shots do not yet have a context. This is provided by the preceding and following shots once they are edited into a production of some kind. Thus the shots need to be indexed as individual entities unrelated to anything else. The only useful way to do this is simply to name the persons, objects, or events seen in the image.

Television newsrooms represent the other case in which shot-by-shot indexing is necessary, this time for the functioning of the newsroom. News events tend to grow, over the period of a day (a gala event), a few days (a factory fire), weeks (an election campaign), months (weather), or years (a war), building on what has already happened. Newsrooms usually have trained searchers on location in the newsroom, who need to be able to hunt down material in a matter of minutes, sometimes even seconds. Because the material usually (but not necessarily) has to do with previous events that are part of the story, there is context. At a primary level, the indexing can be carried out like that of a stockshot library, that is, particular to individual shots. In addition, however, other layers of indexing can be added, for example to relate the shot to its neighbors in the day's shoot, to the events of the previous day, to the story at large, or in a more global context, such as with links to other stories that are related in some way.

In addition, a trend is emerging that will extend in the coming years the pool of moving images cataloged and indexed at the shot level. Large collections gradually being digitized and coming on line will make available many more moving images that can be recycled in other contexts. An interesting example of this is the Institut national de l'audiovisuel (National Audiovisual Institute, INA) in France.^[13] Created in 1975 following the breakup of the national broadcaster (Office de radiodiffusion télévision française, ORTF), INA became the official repository for French radio and television when the legal deposit for these was applied starting in 1995. As of 2007, INA had 130 km of shelving space filled with radio and television programs, covering 60 year of radio and 50 year of television. INA's collection is now the largest digitized audiovisual collection in the world. Much of it is already online, and the rest is gradually becoming available.

INA has long practiced shot-level indexing of its collections, but now that the moving image is available online, a mutation is occurring. Instead of simply maintaining their traditional role as audiovisual documents, these take on the additional role of containers from which fragments can be taken for use elsewhere. In this emerging context, today over half of INA's 250 document professionals have taken on editorial duties, packaging these fragments in new ways. Thus the coherence of the original document becomes a single layer of a much more complex process whereby the shots they contain become new resources as they are reconfigured in new uses.

Accompanying this process, new metadata is created to document the new context.

We can expect to see this kind of activity become universal practice as other large national collections become available online, offering direct access to the moving image. Use of such collections will probably increase considerably because the shot-level metadata will make useful material easy to find in a number of different contexts. Similarly, the potential user base will be greatly broadened because the networked environment offers the possibility of worldwide sales.

Frame-Level Indexing

At the finest, most specific level individual frames need to be indexed, usually in specialized situations such as for scientific or forensic purposes. For example, indexing describing specific objects and their movement might be used in the case of scientists wishing to study the eruption of a volcano, popcorn popping, cell division, and so on. Forensic uses include the Zapruder film of the assassination of U.S. President John Kennedy, determining the cause of the the space shuttle Challenger exploding, or analysis of the planes crashing into the twin towers of the World Trade Center in New York on September 11, 2001.

This level is also of interest to filmmakers, especially animators, who through their work become intensely aware of the content of each image, how much the image needs to move to ensure that the eye is fooled into seeing natural movement. Norman McLaren famously pointed out that the important part is what happens between the frames.

TEXT AND IMAGE

A great deal of research is going on in computer science, attempting to teach computers to recognize objects and people with a view to generating the indexing automatically. There is some hope that eventually techniques will be developed that will permit this to happen, but progress is slow. Even with still images, the technique of identifying one or more key images, then asking the system to "find me more like this" often yields results that are so off the mark as to be amusing. Only in highly controlled situations are any usable techniques available. However, with so many researchers working on the various problems connected with boundary detection, object recognition, perspective, proportions, spatial relationships, and so on, there is hope that eventually the complexities of these problems will be modeled adequately and that these so-called "low-level" techniques (statistical manipulation of pixels to generate semantics) will make a significant contribution to moving image retrieval. In the best systems, these will work in conjunction with the "high-level" techniques (humans attaching semantic information to images). The discourse in the literature of computer

science in this regard most often sees text as a messy problem to be eliminated in favor of fabulous computer techniques that will do the job much better. However, when we consider indexing both still and moving images for storage and retrieval, it quickly becomes clear that text and image are inextricably linked.

We need to use words to retrieve images, and words will remain an important contributor to retrieval strategies. Text is indeed the messy problem computer science researchers identify, but to eliminate it would be to throw the baby out with the bathwater. Text will always be necessary for retrieving images for the simple reason that a great deal of information useful in retrieving images from databases is not available from the images themselves. What is the name of that river in the background? Who is this actor hiding in a pumpkin costume? Is this an actual street scene of the Liberation of Paris or a reenactment? Is that really the campus of Harvard University as it says on the plaque, or is it another campus, or a studio set? What street is that church on? In what city, in what country? Documentary material especially needs text to explain the content of the image. Why is that man crying? How did that child lose its leg? Why is that dog so happy? Where are all those people going? What's going on here?

Using text to get at images is a different problem from that of using text to get at text. In the latter case, direct searches on useful terms can be conducted. The software simply looks for a match. As another layer of search capacity, text queries can be filtered through vocabulary management tools such as a thesaurus or classification to get at other text representations associated with the search string.

With images, however, a cognitive transfer takes place. The indexer looks at the image, and identifies what are the indexable objects. This is akin to assigning meaning to people and objects we encounter in everyday life. We feel a need to identify anything that comes into view, and we use words to do it. Walking along the street, we see a siamese cat approaching and say to ourselves something like, "oh, that's a Siamese cat." If we cannot name the object directly, we are puzzled, and fish through our minds for what it might be if we do not recognize it, and what it is called if we do. We do so in order to satisfy our need to be able to slot everything into some kind of category and thus resolve the discomfort. If we are not able to identify the object or to find some kind of explanation for it, we might erroneously decide it is something else, or ask another person to explain what it is. In extreme cases, fear takes over and we panic.

The phenomenon of dealing with unfamiliar reality is often used as a premise in films about people transported to another century or to another planet. The everyday reality is so different from what they know that the characters need to climb a steep learning curve just to be able to function. When objects or other subject matter are not identifiable, as in fantasy films or with special effects,

usually it is because the characters do not yet know what they are either, and in due time an explanation will be given to both the characters and the viewers. A similar situation involves a special culture (say, *Star Trek*) with its own language and conventions, which are known to aficionados but not necessarily to outsiders.

In practice, however, and with ordinary images from everyday life, naming objects is quite easy and direct. Indexers do not need to agonize over finding the best indexing terms, because indexing involves simply naming the persons, objects, or events being portrayed. Things may have more than one name, but if a list is made, the pool of readily available names for an object is quickly exhausted. When all the useful terms are attached to images, the images are retrieved using any of the terms assigned. A number of studies have shown that professional indexers and ordinary users assign the same terms to images of everyday, easily recognizable people, objects, and events. We wouldn't expect an untrained person to be able to index a book adequately, so why are untrained people so good at indexing pictures? The explanation seems to lie in the nature of the material. The objects are common to everyone's reality, and they do not have more than a few names, so that they are easily identified and named. This phenomenon probably explains, at least partly, why Web sites such as Flickr, YouTube, and MySpace work so well. Users find things readily because the useful keywords to assign to them are obvious. Indexing a book, however, involves a lot of synthesis, interpretation, grouping, and so on. In short, it is rigorous intellectual work.

We note in passing that the same indexing approach used for pictures applies to sound. We hear something, and want to know what it is. Once we have attached a name to it, the issue is resolved and we are satisfied. If we cannot name it, we seek help in identifying it. Libraries of stock sounds use the same indexing approach as libraries of stock images, that is, either categorizing the sounds into useful themes or attaching useful keywords to the sounds, or both.

Interestingly, since images are representations of objects and not the objects themselves, we can be easily fooled. Decors in movies, for example, can be shot on location or constructed as sets, or filming can take place in a location that is not the location represented. Thus, in indexing some collections of moving images, provision needs to be made for the real location and the represented location, the real time at which the image was shot and the represented time. Viewers' minds can also be stretched somewhat with representations of the characters. However, the representation of well-known people in movies has to fall within boundaries to which viewers can suspend disbelief. Sounds, of course, can also be faked, and in fact this practice is widespread in movies, to the point where the profession of a Foley artist is to do just that. Again, the database structures of systems that manage this kind of

information may need to take this into account, depending on their users and the needs of their users.

Recycling Text

Because of the high costs in both money and time when indexing is created by humans, efforts in information science research are focused on finding ways to reuse text that was created for other purposes in the processes of producing moving images. This involves recycling useful keywords and attaching them to individual shots. An obvious example is the use of closed-captioning subtitles, created for the deaf and for people with hearing loss. These transcribe, more or less faithfully, everything that is said by anyone on or off camera. In some subtitling and closed-captioning systems, additional sound information needed to understand the action is indicated, for example that a telephone is ringing or that there is a knock at the door, not seen in the image. Additional cues advise who exactly is speaking, that someone is not speaking but singing, that sound is coming from a radio, loudspeaker, or other device, what someone is thinking, and so on. When connections are made between closed-captioning text and the corresponding image, a user who remembers a snippet of dialogue can very quickly get to the image during which the dialogue was recited.

Note, however, that the text of closed-captioning has to do with the spoken word. It does not describe the image. Another technology, audio description, adds a special sound track for users of moving image materials who are blind or who have some vision loss. A describer recites text that offers descriptions of what is happening in the image. Users can already decode the story to some degree by following the dialogues and other sound information, but the audio description text uses words to describe aspects of the image that are essential for understanding the action. From the point of view of moving image indexing research, we might say that audio description text complements the closed-captioning text, in that the audio description indexes the image and the closed-captioning indexes the sound.

These two examples give an idea of the potential of recycling text created for other purposes in indexing moving images. There are many, many other kinds of text produced in the process of making moving image documents, and the challenge is to harness these in a way that automates the process of indexing. Other useful texts include the shooting script broken down for the shoot, in which all the decors, props, costumes, accessories, lighting, weather, and so on are described, the editor's logs, created early in the process to help the editor identify individual shots, producer's notes, director's notes, and camera reports.

As is the case with the creation of every other kind of information, moving image production is rapidly moving to a digital environment. Although it is doubtful whether

moving image production will ever be entirely digital, it will come very close to that goal. The dream of mining for indexing terms the computer systems used to manage all the textual information needed to make a film is a worthy one. If techniques for parsing and tagging text identified as useful for indexing the image are applied to existing text, and links made from it to the corresponding image, systems that offer access to individual shots can be built.

MULTILINGUAL INDEXING

In the context of globalization, multilingual indexing of moving images is becoming more and more important, even unavoidable. The use of collections that are searchable via the Web can be greatly increased if people all over the world can find them using their own language. The notions that everyday objects are common to everyone's reality, and that they do not have more than a few names at most, can be exploited to automate the indexing of still and moving images in many languages, once they have been indexed in one language, theoretically any language.

We hasten to add that automatic translation of the names of objects is not the same problem as automatic translation of continuous text. In the latter case, the typical messiness and sometimes outright anarchy of natural language offer considerable challenges, and automatic translation of continuous texts has not yet been modeled well enough to give satisfying results, except in highly controlled situations. However, work on these problems continues apace, and progress is steady. In the case of automatically translating the names of objects, the correspondence between languages is much more direct, and there are no grammatical or idiomatic issues to resolve.

Interestingly, it is not even necessary to index each collection in multiple languages for multilingual indexing of moving images to come about. What is needed is online bilingual or multilingual dictionaries, thesauruses, and other vocabulary management tools such as classifications, ontologies, authority lists, semantic maps, and so on. A sample scenario of how searches could work is this: a system could filter through an automatic translator a query made in any language, put the term sought into all other languages available, with each language search the participating databases locally, gather and compile the results, and return the images to the user. One of our studies in this area^[14] filtered queries in English and French through eight freely available Web translators, to test how accurate they were in producing a correct term in the other language. The poorest performer of the eight still got the correct answer 72% of the time.

Since objects can have more than one name, a method to measure the success of the correspondence between languages needed to be developed. We used a bilingual dictionary. If the term the automatic translator came up with in response to a query from the source language was

one of those listed in the dictionary for the term in the target language, we considered the translation successful. There is good reason to believe this will work well using any languages; however, empirical research that tests across the various families of languages is necessary to prove this conclusively.

What is missing to make automatic multilingual queries possible is infrastructure in the form of online tools and metadata. The online tools involved are the multilingual vocabulary management tools mentioned earlier. A number of these are already available, but not necessarily in multiple languages or with interoperable structures. With time, various interested parties, many of whom are outside the realm of information management, will develop these and put them on line. When that happens, they will be available to exploit.

Exploitation of such tools will be made possible through metadata infrastructure. This involves common or standardized description tools and methods, layers of metadata to make them interoperable, query languages and programming that can exploit the content, and user interfaces that make the behind-the-scenes activity transparent to the user. Available standards and recommendations such as the Dublin Core Metadata Initiative (DCMI), Simple Knowledge Organization System (SKOS), Material Exchange Format (MXF), JPEG2000, and the Resource Description Framework (RDF) are the kinds of tools such a metadata infrastructure needs to include. However, these are not yet mature enough or implanted widely enough to make the dream of universal access to moving images come true.

INDEXING OTHER THAN SUBJECT INDEXING

In information science, the term “indexing” commonly refers to subject indexing. However, more broad definitions of the term include any indicator or other way to point to something, aptly illustrated by the index finger, the finger used to point, apparently the origin for the term. In indexing moving images, a number of access points other than the subject are especially useful in narrowing down long lists of images returned in response to a query. For example, if only a particular type of shot will do, the user might as well specify this in the original query, thus eliminating shots that do not conform and increasing the pertinence of those that do. Such a search strategy supposes that the shots have been indexed using such access points. Following is a discussion of some of these.

Camera angles: How the camera is looking at the object of interest in the image is often important, and sometimes critical. Ready examples of this include aerial views, close-ups of faces, or satellite images. A number of relatively standardized lists of types of shots are available, reflecting terminology in various national and other contexts, and any of these can be used as an authority list.

Alternately, codes can be derived from such lists. By attaching these to records of individual shots, access by camera angle becomes available to the user.

Colors: In some kinds of collections, for example specialized collections of any kind of object such as cars, museum objects, clothing, animals, and so on, colors can be critical for the searcher. Dominant colors can be indexed fairly easily using standardized lists, although this can become complicated by the great number of nuances possible. In each situation, a decision on the limits of this needs to be made. Interestingly, in the low-level approaches to indexing, color is one thing searching algorithms can calculate easily, so that in hybrid systems words do not have to be used to provide indexing of colors. For example, the system can calculate the number of pixels within a range of color codes, and return images in which the desired color is dominant.

Time periods: As we noted earlier, there is real time (when the shot was actually taken) and represented time (in scripted productions, when the action takes place). Thus a shot might be taken in 2005 but the action in the film takes place in 1724. If both these dates are indexed, searches on the date become available to the user. Some time periods we might wish to represent are not so precise, so that coding for more vague periods such as the seasons of the year, various moments in a day, or various historical groupings of a number of years is also useful. At the other extreme, sometimes very precise times, including a fraction of a second on a particular date also need to be expressed. A number of coding systems are available for expressing these, for example, the tables available at the end of the Universal Decimal Classification (UDC), which provide for all such cases and more, thus offering a controlled vocabulary that can be used for this purpose.

Geographic spaces: Similarly, there is real location (where the shot was actually taken) and represented location (in scripted productions, where the action takes place). Thus a film might be shot in Argentina but the action in the film takes place in Ireland. Again, separate fields in a database to represent these concepts will allow users to search on either. And again, a number of code lists are available, including a UDC list. Such lists are particularly useful since they permit the expression of political entities (e.g., country names and regions within a country) but also take into account geographical features which cross political borders, such as rivers, mountain ranges, and so on. With the global positioning system (GPS), it is also possible to generate coding to pinpoint precise locations.

Emotion: Indexing human emotions represented in moving images can be helpful to some users, although such indexing is rather hazardous because of the ambiguity involved. It is not always clear to the indexer which emotion is being expressed, especially if there is not enough context. However, in collections where such indexing is desirable, imperfect indexing is still much

better than no indexing at all. As with every other kind of indexing, use of some kind of controlled list is desirable, even if it is an in-house list.

Lighting conditions: Whether a shot is taken indoors or outdoors is often significant. Indoors, some description of the degree of luminosity, even broad categories can be helpful, such as very bright studio lighting at one extreme and dim lounge lighting at the other. Outdoors, weather conditions are often useful to describe. Particular times of day can be covered using time period coding, but this does not cover weather and lighting conditions. The sky can be black at high noon because a thunderstorm is about to break. Managers of individual collections will need to decide what level of detail is appropriate. In general, however, a simple, controlled list of lighting conditions is probably enough.

Other indexable special conditions: A number of special conditions are indexable, again for their value in eliminating shots that do not meet such a requirement. These include underwater material, images taken by satellites or shot from space, images shot using infrared cameras or heat-detecting cameras, images reconstituted using computer technology, or anachronistically altered images modified to include a present-day person alongside people long since deceased. Other categories include images using special effects or images shot with special equipment such as fisheye or panoramic lenses.

In addition, we can imagine any number of kinds of special collections of images, for example, images of only mushrooms, stones, cars, types of screws, or furniture. Or collections of microscopic images of diseases affecting cells, forensic photographs, technical aspects of spacecraft or bridges or roofing, and so on. In these cases, the indexing problems will be centered around specialized vocabularies for describing the image content and the level of indexing required.

IMAGE TAGGING

Much has been made of the now rather hackneyed expression “Web 2.0,” referring to services available in the context of the evolution of the World Wide Web. Nevertheless, services associated with this concept have been at the heart of the “democratization” of information management, based on the principle that information belongs to everyone and should circulate freely. From the point of view of access to information, this means that technology is loosening the grip of the controllers of information and making it available to everyone. From the point of view of indexing information, this notion challenges the “stranglehold” professionals have on how information is organized and managed. For better or worse, a number of phenomena have sprung up in this context and are now broadly practiced, including communal writing in the form of wikis, building communal classification

structures in the form of folksonomies, and journalism in the form of blogs. The phenomenon that concerns us here is user-based indexing, commonly referred to as tagging.

Professional indexers strive for rigor and consistency, and users of the work they produce depend on these qualities in order to do their own work. The practice of indexing both still and moving pictures by untrained persons results in varying quality of indexing. Whether user tagging should even be called indexing or not is open to debate. In discussing the issue, it is important to distinguish among various types of images, because each type has its own indexing needs. For indexing purposes, it is convenient to divide the vast world of images into three categories: art images, documentary images, and “ordinary” images. For our purposes here, the same categories can be used for moving images, although a number of additional useful categorizations are available for these latter.

Art images are interpreted, analyzed, and discussed at length. Thus it is easy to argue that specialized skills are required for indexing them. Indeed, specialized skills are necessary even for looking at them and understanding them. Large bodies of scholarship can build up around even a single painting. Biographical information about artists is often included as part of the discussion. Controversies develop and generate much additional documentation. From an information management point of view, systems for still art images have been constructed mainly to support museums and art history programs in universities, and the way art images have been indexed reflects this perspective. Since the discussion of the levels of interpretation of still art images is outside the scope of this entry, suffice it to say here that historically they have been indexed at an intermediary level of interpretation, avoiding naming individual objects as we find with documentary images and ordinary images. However, now that the relatively recent networked environment has become available, the need to name individual objects in art images is more pressing than ever. In addition, in order to assist scholars, there is a need to gather all the material, whether it be textual, still or moving images, or sound, so that rather complex information systems are needed to manage information about art. Moving images in the form of art films, films about art, films made by artists, and films about artists form part of this corpus and are subject to the needs arising from the same kind of complexity.

However, documentary images are not subject to such needs. The indexing for documentary images involves identifying persons, places, and events by name, and offering explanations that help interpret the image. Although we usually associate documentary images with current events, political, or news items, in the broader sense family photos and videos also fit into this category since they chronicle the same type of information, albeit on a more local, more circumscribed scale. It is easy enough to see the value of indexing such images for those who participated in the event, be it family members or

members of a social group, and indeed, these may be the ones best qualified to do the indexing. Similarly, the filmmaker and crew of a documentary may be the ones best equipped to identify and explain the content of the image, since they are so intimately associated with making arrangements for the shoot, are witness to the event, and have made the decisions about exactly how to capture it on film or video.

“Ordinary” images include pictures of animals, flowers, everyday objects, generic scenes, and so on. Examples of the use of ordinary images include illustration, decoration, or as teaching aids in a variety of contexts. Ordinary images can include anything that can be photographed, and the photographer is the “author” or creator of the image. However, in opposition to the situation with art images, the author or creator of an “ordinary” image is not usually important or significant to the user. In general, ordinary images can be indexed by anyone, based on the notion of access to a common reality, since the indexing activity consists of naming the persons, objects, or events in the image. As we mentioned earlier, several studies have shown that untrained users pick the same indexing terms as professional indexers for such images.

For purposes of managing collections of images, it is helpful to note here that the three categories of art, documentary, and “ordinary” images are not necessarily mutually exclusive. For example, an ordinary image can become part of a work of art if an artist decides, for example, to paste a magazine photo of a cup of coffee into a collage. A photographer might think she is merely documenting a person or an event but the resulting photograph is so perfect as to be considered art, or with time become famous for some reason never intended at the outset. In other cases, an image might belong to more than one category simultaneously, for example stock footage of office workers (“ordinary” images) might be sold to makers of corporate videos but for the family and friends of such workers (or actors) the footage also documents their lives (documentary images). We can also imagine the same piece of material ending up in an art film (art images).

Whatever the type of images, the problem remains in using a controlled vocabulary to do the indexing. However, for images other than art images, it is not much of a problem. If we remember that the basic function of indexing is to point to something, then we need also to remember that there can be more than one way of pointing to something. If a number of users add their own tags to images, the possible names for any object are soon covered, and any of the names will retrieve the image. The main function of a controlled vocabulary is to gather synonyms and variants and select a single term for indexing each concept. The reason we bother to do this is largely associated with technology. In the case of controlled vocabularies, the arguments for using them are still sound, but if the technology available skirts the problem they are

designed to solve, do we still really need them? As an example, PREserved Context Indexing System (PRECIS) indexing fell by the wayside as computer technology developed because the complexities involved in using the system were no longer necessary. PRECIS made use of software to construct indexing strings and to shunt the strings so that each key term could appear as the entry point in an alphabetical list. However, PRECIS indexing was developed to produce print indexes. Since databases can be searched on any field, it became unnecessary to permute the indexing strings to make available all the entry points to them.

Another discussion in this context is the use of a thesaurus to index ordinary and documentary pictures. The rise of the thesaurus as an indexing tool was largely to do with arranging into semantic networks the vocabulary of specialized areas of endeavor. The notion of using a thesaurus to index a general collection of still or moving images goes against the idea of the thesaurus as a tool for managing the vocabulary of particular areas of endeavor, and supposes the existence of a general thesaurus. Surprisingly, the idea of building a thesaurus for anything that can be photographed is not so farfetched as it seems. A number of moving image collections have built such a tool for indexing their collections. A published thesaurus, the *Thesaurus for Graphic Materials*, was built for indexing documentary and ordinary still images, and is widely used for indexing both still and moving images. A few thousand terms seem to be enough to make such a tool useful, since term creation in this thesaurus and a number of in-house thesauruses seems to level off after a few thousand words.^[15]

Another question is how many terms should be attached to each image. As Dizard (2004)^[16] puts it, “a picture is worth a thousand words, but which ones?” This is another question related to technology, and the reason for determining limits had to do with the amount of work involved in managing information systems. The point here is that there are no longer technical or managerial reasons for limiting this number. A number of studies have shown that one, two, or three terms are often enough, but this of course depends very much on individual images and on user needs. Today, the answer to the question of how many indexing terms to use is: as many as are useful.

Ultimately, the issue of indexing both still and moving images is economic. The cost of professional indexing is inevitably high, so it seems reasonable to reserve it for art images. For documentary and “ordinary” images, the implicit argument is that indexing by nonprofessionals is better than no indexing at all, also that it is “good enough.” In addition, maintaining the tools used for such indexing adds to the costs. Since indexing ordinary and documentary pictures involves attaching names to persons, objects, and events, tagging these with keywords might well be good enough. In the end, it is a moot point, since tagging is free. If costs were involved, it is doubtful whether much tagging would occur at all. Finally, since the term tagging

is associated with the practice, purists can easily distinguish between what is “properly” indexed and what is merely tagged.

THE FUTURE OF MOVING IMAGE INDEXING

By using automated techniques and by exploiting text created for other purposes, shot-level access to moving images could become readily available. How this will happen exactly is a matter of conjecture. We note, however, that already computers can easily detect when a new shot is starting because there is a radical change in the image content from one frame to the next when this happens.

Thus a production can automatically be divided into individual shots. We note that distributors of movies in DVD format usually provide chapter divisions with identifying names, allowing users to readily access individual parts of movies. Television programs also have logical divisions, and these are provided in television archives. For example, a current events show will have a number of reports, each cataloged separately and related to the whole. Thus the problem of automatically identifying the useful divisions of moving image productions is already solved. Automatically attaching indexing terms to these divisions is the next problem we need to address.

As we noted in the section on “Shot-Level Indexing,” some situations use shot-level indexing by humans. How to attach keywords (synonymous for our purposes with tags and indexing terms) to sections of moving image productions and to individual shots automatically has to do with recycling existing text in a digital environment. As we noted in the section on recycling text, a number of text sources created for other purposes in the processes of production are available. Techniques used in linguistics such as shallow parsing can identify nouns and noun phrases. These are known to be the parts of speech indexers use to represent moving images at the shot level with verbs, adjectives, and adverbs appearing only rarely.

At some point in the not too distant future, production of moving image documents will be nearly entirely digital. It is already largely so. Imagine, then, large modular production databases which house not only the image and the editing information, but also virtually all the text created during the production processes. Imagine further extending the functions of such production databases to include archiving the material. By mining the text modules, parsing the text, and attaching keywords to the corresponding images, all these activities being stages of executing an algorithm, we can imagine indexing individual shots, sequences, scenes, and chapters automatically.

In addition, the work being done in this area by computer science researchers will eventually come to fruition. Because of the immense complexity involved in automatically identifying objects and relationships among them,

then attaching semantic information to them, such work is largely experimental and poorly performing at present. However, the day will come when the low-level approaches and the high-level approaches will be usefully combined in hybrid systems that will most likely offer the best performance for retrieval of moving images. We can imagine attaching smart user interfaces to such systems so that they will be able to suggest search strategies using one or the other approach, dynamically, depending on contextual information.

If we add to this equation improved infrastructure that permits the ongoing deposit online of movies and television shows, as well as vast quantities of home video, along with the possibility of downloading all this and viewing it on computer screens, the picture broadens further. We can imagine Web-based systems that search all this material, along with its indexing metadata added automatically via the low-level and high-level approaches, including text in many languages, returning precise results to users of such systems. When that day comes, users will be able to get answers to questions that today cannot even be asked, and a new horizon of possibilities for study and use of the planet’s visual heritage will appear.

CONCLUSION

This entry has tried to explain some of the issues surrounding moving images. Although large collections of these have been built since moving images first appeared on film in 1895, methods for organizing such collections remain largely undeveloped, at least when compared to methods for text collections. Apart from their relative recency, moving image collections are not organized so well because they have a number of very different characteristics and thus are not amenable to the same kinds of techniques.

We noted that a number of levels of access need to be provided, depending on the context of the collection and the needs of its users. These range from relatively simple cataloging of DVDs of commercial films to frame-by-frame analysis in scientific and forensic contexts. In some conditions, nonsubject access points are sometimes more useful than subject indexing terms, and a number of these access points are available for moving image documentation. Although a great deal of research in automating the indexing process using low-level approaches is being conducted in the field of computer science, the relationship between text and image is an essential one that will persist. Thus the research in information science focuses on automating the generation of indexing terms from text created for other purposes during the processes of producing moving image documents.

In a global environment, multilingual indexing is an issue gaining prominence, and work on learning to exploit online vocabularies in many languages contributes to automating the highly desirable provision of access to

moving image materials in many languages. The development of Web-based tools of many types, including controlled vocabularies, semantic networks, and bilingual and multilingual dictionaries and thesauruses will foster the acceleration of success in this area.

The need for building systems that can interact with other systems in a networked environment is the strongest force driving the work on information management systems for moving images. Necessarily complex, such systems involve a great deal of thought, planning, discussion, and development. The need to exchange information rapidly and efficiently means that the more interoperable individual systems are with other networked systems, the easier it will be for those involved to accomplish their work. Such goals are eminently worth striving for.

Multilingual Information Access

Douglas W. Oard

College of Information Studies, University of Maryland, College Park, Maryland, U.S.A.

Abstract

This entry describes the process by which systems can be designed to help users find content in a language that may be different from the language of their query. The discussion of the relatively narrowly construed technical issues that are often referred to as Cross-Language Information Retrieval (CLIR) is situated in the context of important related issues such as information-seeking behavior, interaction design, and machine translation.

INTRODUCTION

The central thesis of Tom Friedman's book *The World is Flat* is that we now live in a world in which technological innovation is creating opportunities for more seamless global interaction than has heretofore been possible.^[1] It is important to recognize that "technological innovation" encompasses far more than mere technical innovation—equally important is our ability as a society to learn to productively use the technical capabilities that we can create. This entry examines one such technology: helping users to find information in ways that "flatten" language barriers. In keeping with what is emerging as common usage, we refer to this challenge as Multilingual Information Access (MLIA).

This word "multilingual" can be used in many ways, so let us start by saying what we mean. A multilingual collection is a collection of documents that contains more than just a single language (e.g., English and Chinese). These documents may each contain just one language, or some of the documents might contain words from more than one language. Our interest is in helping a searcher to find the documents that they seek, regardless of the language in which they are expressed. For simplicity, we will assume in this entry that documents are expressed in writing and stored as e-text (i.e., as digital sequences of character codes), but similar approaches have been applied to scanned documents and spoken word collections, and might in the future also be applied to visual languages (e.g., American Sign Language).

Who needs MLIA? We can envision at least two user groups. Perhaps the most obvious is so-called polyglots—people who are able to at least read (and perhaps write) more than one language. For example, more than one billion people who know at least some English are native speakers of some other language. Polyglots can benefit from MLIA in at least three ways: 1) they can find

documents in more than one language with a single search; 2) they can formulate queries in the language(s) for which their active vocabulary is largest; and 3) they can move more seamlessly across languages over the course of an information-seeking episode than would be possible if documents written in different languages were available only from different information systems. Monoglots (those who know only a single language) form a second important group. For example, many Americans can read only English, while many citizens of China can read only Chinese. Those populations essentially live in different worlds, worlds that MLIA can help to bridge.

MLIA always involves Cross-Language Information Retrieval (CLIR), in which queries in one language are used to find documents in another. When the user cannot read the document language, some form of translation service will usually be needed. This might be as simple as automatic translation of short snippets, or as complex as on-demand translation by a subject matter expert. There are, however, also cases in which adequate results might be presented without translation. For example, someone who knows only Japanese might search a collection of newspaper photographs that are indexed using only English terms and still easily recognize which of the resulting photographs would best meet their needs.

The remainder of this entry is organized as follows. The next section places MLIA in historical perspective and explains (or at least interprets) how and why modern techniques for MLIA evolved in the way that they did. The section "Cross-Language Information Retrieval" then describes the present state of the art for CLIR, the key technical capability in all MLIA applications. The section "The Rest of the Story" builds on that, broadening the coverage to address interaction design and information-seeking processes. Finally, "the entry" concludes with a brief survey of the present state of practice and elucidation of some important open questions.

A BRIEF HISTORY OF MULTILINGUAL INFORMATION ACCESS

Gaining access to information in unfamiliar languages has always been an important problem. The intense technological competition that was emblematic of the Cold War in the second half of the twentieth century created a substantial demand on both sides for translation of scientific and technical papers. After some early, and rather disappointing, experiments with automatic translation, the United States National Research Council recommended in 1966 that basic research continue, but that the work of people, rather than machines, provide the principal means for making foreign-language information accessible for the foreseeable future.^[2] This recommendation fostered the development of a part of the information industry that focused on translating scientific and technical literature and indexing those translations. Journal articles and so-called gray literature (e.g., technical reports) were translated either prospectively or on demand by a number of organizations, and the World Translations Index (and its predecessors) evolved to provide the needed indexing service for speakers of English.

The economic growth and linguistic diversity of Europe in the second half of the twentieth century provided the impetus for the second major innovation, the development of multilingual thesauri. Oard and Diekema surveyed the genesis of this work, from the first published report (in 1964 from Germany) through publication of the current (1985) version of ISO Standard 5964, which recommends techniques for construction of multilingual thesauri.^[3]

Substantial reliance on human translation and thesaurus-based indexing were good choices at the time, but three key events dramatically changed the opportunity space. The most obvious was the end of the Cold War, which resulted in substantial changes in national investment strategies. The International Translations Centre ceased operations in 1997 with the publication of the last volume of the World Translations Index, citing declining demand for their services that resulted from increasing adoption of English as a lingua franca for scientific communication and from declining funding for information science more generally.

The second key event was the rise of the World Wide Web, and in particular the widespread adoption of Web search engines such as Lycos, AltaVista, and Google. Furnas et al. had remarked on what they referred to as the “vocabulary problem” in human–system interaction, observing that “new or intermittent users often use the wrong words and fail to get the actions or information they want.”^[4] Although the fuzzy-match full-text search capabilities of the 1990s-era Web search engines were far from perfect, experience with that technology began the process of incrementally shifting expectations away from

intermediated thesaurus-based search and toward end-user “natural language” search.

The third event, which attracted far less attention at the time, was a remarkable payoff from the investments in basic research that the National Research Council had recommended. Earlier approaches, based on hand-coded rules, had proven to be problematic because the rules could interact in ways that were difficult to anticipate. As a result, at some point adding additional rules in an effort to improve things could actually reduce translation quality. In 1990, a group at IBM Research first published a radical new technique based on one simple idea: machines can learn to translate by using statistical analysis to identify regularities in large collections of translations that were generated by people.^[5] Importantly, as more examples are provided, translation quality improves. This “data-driven” approach, which came to be called statistical Machine Translation (MT), is thus well matched to a networked world in which assembling ever-larger collections is increasingly tractable.

These three events, unfolding together in the last decade of the twentieth century, came together to transform both the need for, and the opportunities to provide, automated techniques to support multilingual information access by end users. The spark that ignited the process was a 1996 workshop at an information retrieval conference in Zurich.^[6] Early techniques were limited by their reliance on online bilingual dictionaries, but techniques based on statistical machine translation were soon introduced. As described in the next section, this ultimately yielded fuzzy-match full-text search capabilities that accommodate language differences between the queries and the documents remarkably well. End-user search requires more than just accurate ways of finding documents that may be useful, however. Equally important, the user must be able to recognize those useful documents, understand their contents, and (sometimes) draw on that understanding to progressively improve their queries; the section “Conclusion” addresses those issues.

CROSS-LANGUAGE INFORMATION RETRIEVAL

The core capabilities that enable MLIA are indexing and query processing for CLIR. Indexing proceeds in three stages: 1) language and character set identification; 2) language-specific processing; and 3) construction of an “inverted index” that allows rapid identification of documents which contain specific terms. Sometimes the language in which a document is written and the character set used to encode it can be inferred from its source (e.g., *New York Times* articles are almost always written in English, and typically encoded in ASCII) and sometimes the language and character set might be indicated using metadata

(e.g., the HTML standard used for Web pages provides a metadata field for specifying the character set). In other cases (or to confirm an initial guess), a very simple form of content analysis can be used to identify those boundaries languages and character sets. The usual approach is to count the frequency of character sequences, and then to guess the language based on similarity to counts computed in the same way for documents written in a known language. For example, the first sentence in this paragraph would yield the following 3-byte sequences: “the”, “he”, “e c”, “co”, “cor”, “ore”, etc. The technique is easily extended to accommodate multibyte character encodings by counting bytes rather than characters. Language and character set classification using this technique is remarkably accurate (typically well over 95%) for any text that is at least as long as a typical paragraph, so language switching within a single document can sometimes also be detected using this technique.

Once the language and character set are known, the character set can be converted to a standard representation (often Unicode) and two types of language-specific processing are then typically applied: 1) tokenization to identify the terms that could be indexed; and 2) stopword removal to identify terms that need not be indexed (for efficiency reasons). For English, tokenization typically involves splitting on white space and then using rule-based techniques to remove common endings (so-called “stemming”). Identifying “word” boundaries is more complex in “freely compounding” languages such as German, Finnish, and Tamil, and in “unsegmented” languages such as Chinese. Of course, the spoken form of every language exhibits this same tendency to run words together without pauses, so techniques similar to those used in speech recognition for identifying words can be used to identify. The basic idea is to draw on two sources of evidence: we can know most of the words that exist in the language (using a dictionary), and we can guess which word sequences might make sense (e.g., from statistical analysis of word usage). Using these ideas together would tell us that the word “Washington” found in a German document might (from the dictionary) be segmented as “was,” “hing,” and “ton,” but (from usage statistics) that such a segmentation would be unlikely to be correct—in this case we would therefore index the unsegmented word “Washington.”

The inverted index used in CLIR is similar in structure to an inverted index used in any information retrieval system, but the information stored in that index may be different. Conceptually, an inverted index includes two parts: 1) a lookup table stored in fast main memory that can be used to rapidly find the “postings” for a specific term (i.e., identifiers for all documents containing that term); and 2) The postings file, which (because of its size) must be stored on the (much slower) hard disk. One of the most important advances in information retrieval system design in the past decade was the widespread introduction

of automatic compression techniques for the postings file. Because these techniques are tuned to achieve the greatest compression for the most common terms, stopword removal is no longer essential as an efficiency measure in monolingual applications. In CLIR, however, deficiencies in the translation technique can sometimes yield inappropriate results for translation of very common words. Stopword removal is therefore still common in CLIR applications.

The most obvious distinguishing feature of CLIR is that some form of translation knowledge must be embedded in the system design, either at indexing time or at query time. Essentially, three approaches are possible: 1) translate each term using the context in which that word appears to help select the right translation; 2) count the terms and then translate the aggregate counts without regard to the context of individual occurrences; or 3) compute some more sophisticated aggregate “term weight” for each term, and then translate those weights. Somewhat surprisingly, while the first two of these work about equally well in many cases, term weight translation is typically not competitive.

If the user will ultimately require a machine-generated translation, and if that translation is always into the same language, then a strong case can be made for translating every term in context at indexing time. In its simplest form (which is often adequate), this essentially amounts to simply running a full machine translation system as a preprocessing step prior to building the inverted index. Efficiency arguments against this approach would be hard to make: a translation system fast enough for responsive interactive use at query time would also be fast enough to process every document in all but the very largest collections at indexing time.

When full translation is not needed (e.g., for polyglot users), or when translations into many different languages may be needed to serve a linguistically diverse population, indexing documents using the terms in their original language is typically the preferred system architecture. In this case, considerable efficiency improvements can be obtained by translating term counts rather than term occurrences. The basic approach, first discovered by Pirkola^[7] (SIGIR, 1998), is to count every possible query-language translation of each term as having been found in the document. Subsequent refinements resulted in further improvements from using translation probability for individual terms to estimate partial counts^[8] and from aggregating translation probabilities for synonymous terms.^[9] Regardless of the details, the key idea is to compute “term weights” in the query language rather than in the document language. Many of the commonly used term weighting formulae give more weight to rare terms than to common terms, which comports well with the way professional searchers are trained to enhance the precision of their search using terms that they expect will be highly specific. Since specificity is a feature of the query, it

makes sense that computing term weights in the query language would work well.

Among all of the advances in CLIR, none has had anywhere near as large an effect as accurate translation probabilities. The best reported results for systems that lack any notion of translation probability (often called “dictionary-based” techniques) are in the range of 70–80% of what would have been achieved using queries written in the same language as the documents. (These results are normally reported as an average across many topics. The most commonly reported search quality statistics in the CLIR literature is “average precision,” which is designed to emphasize the density of relevant documents near the top of a ranked list where most searchers are expected to focus their attention.) The best reported results for systems that use translation probabilities well is closer to 100% of what would have been achieved using same-language queries.^[9] It is worth taking a moment to consider what that means—today, we can build systems to search French documents that work (approximately) equally well regardless of whether the query is written in French or in English! Of course, for any specific query the system might do better with French or with English, but on average over repeated use the best systems that can be built today do about equally well in CLIR or monolingual applications.

The key question, therefore, is how to obtain sufficiently accurate translation probabilities. It turns out that this problem was solved for us as one part of statistical MT.^[5] The key idea behind statistical MT is that a machine that knows very little about language (e.g., just how to recognize a word) can learn to recognize (and later replicate) patterns of language use by counting what happens in very large collections of examples of language use. Specifically, we give our machine an enormous collection of examples of actual translations (e.g., “man in the moon” and “l’homme dans la lune”) and ask it to find the most common alignments of individual terms (e.g., “man” and “l’homme” in this case, but “l’humanite” for “man” in “the evolution of modern man”). If the examples from which the machine learns are representative of the cases to which it will later be applied, the translation probabilities learned by the machine can be quite useful. A full MT system contains additional processing stages, but for CLIR it is often sufficient to simply use the learned translation probabilities directly (with some pruning to suppress the effect of relatively rare random alignments).

THE REST OF THE STORY

There is, however, quite a bit more to the search process than simply automatically creating best-first rankings of documents that the user might wish to examine. Three key questions arise: 1) can people learn to formulate effective queries?; 2) can people recognize useful documents in the

result set?; and 3) can people adequately understand the contents of those documents to meet their information needs? Research on these topics is still in its infancy, and moreover we can reasonably expect that as translation technology improves the answers to these questions may change. There will be, therefore, substantial scope for important Library and Information Science research on these questions for some time to come.

The most tractable of these questions at present turns out to be the second one: people seem to be remarkably good at recognizing useful documents using even relatively poor translations. In 2001, the Cross-Language Evaluation Forum (CLEF) started an annual interactive track (iCLEF) to foster research on these questions. In that first year, the focus was on interactive assessment of topical relevance using machine translation. Representative users (in this case, university students) were presented with a written topic statement in a language they knew well (e.g., English) and a set of news stories in some other language that they did not know at all (e.g., Spanish) that had been ranked by a CLIR system and then automatically translated back into the language of the topic statement. Topical relevance judgments made by native speakers of the language in which the news stories were written were used as a gold standard. On average (over several users, each working on several topics), the searchers who did not know the document language agreed with the native speakers about as often as two native speakers would be expected to agree with each other.^[10]

Together, those studies indicate that recognizing relevant documents using automatic translation of short summaries or of entire documents is usually not a particularly difficult task. Considerable scope remains, however, for future research on optimally combining the technology for summary generation and translation, for analysis of specific cases in which present technology is not meeting user needs well, and for determining how best to present those results to the user (e.g., as several lists or as a single integrated list).

The third challenge, translating documents well enough that the user can understand their contents, is exactly the goal for which automatic systems for machine translation are optimized. Translation quality can be measured in two ways: 1) an “intrinsic” evaluation in which we ask how similar an automatic translation is to something that a human translator would actually create; or 2) an “extrinsic” evaluation in which we ask how well the reader can accomplish some task using the translation. Intrinsic evaluations provide an important way of assessing incremental progress in the design of machine translation systems, but extrinsic evaluation sheds more light on the ability of present translation technology to meet user needs in multilingual information access applications.

The iCLEF 2004 user studies provided an initial extrinsic evaluation of translation quality, measuring the user’s ability to answer factual questions when searching a large

collection of news stories in an unfamiliar language. The results of those studies indicated that (on average, across users) only about 70% of the questions could be answered at all, and that (on average, across users and answered questions) only about 70% of those answers were correct. Considering both factors together, those factual questions were answered correctly about half the time.^[11]

Jones et al. took this approach further, measuring the utility of an improved machine translation system across four source types (newspaper stories, text-only discussion groups, automatically transcribed news broadcasts, and automatically transcribed talk shows) using a reading comprehension test. They reported about 80% accuracy for answers to factual questions, but only about 50% accuracy for answers to questions that called for some degree of abstract reasoning.^[12] From this we can conclude that present machine translation technology can satisfy some user needs, but that further improvements in translation quality will be needed before broadly useful multilingual access applications can be fielded.

The first of the questions posed at the start of this section, whether people can learn to formulate effective queries, is at this point the one we know the least about. The reason for this is simple—to learn very much about this would require long-term studies of real users performing real tasks. But before that can happen we must develop and field real systems capable of supporting those tasks, and those systems don't yet exist. Some insights have begun to accumulate from anecdotal reports of user experiences during structured user studies that have implications for system design. For example, sometimes searchers will recognize a useful term in a translated document and add it to their query, which will only work well if translation of documents and queries are implemented in a consistent manner (which was not the case in early systems). It also seems to be a good idea to inform users when no translation is known for a query term. It is not yet clear how far to take this idea of informing the user—should we show them the translated query? All possible translations for each query term? Alternate translations for some of the terms in a summary or a full document? Perhaps soon we will begin to see studies using Google's new MLIA capability (described below) that will begin to shed light on some of these questions.

CONCLUSION

Adoption of MLIA capabilities in deployed systems seems to have been far slower than the progress on the underlying CLIR technology would support. Deficiencies in current MT systems are undoubtedly a limiting factor in many cases, although applications intended for use by polyglot users would naturally be less affected by those deficiencies. Some cases may reflect a chicken-and-egg paradox: MLIA is needed only for large multilingual

collections, but collection development policies in many cases predate the availability of these techniques. Web search would seem to be a natural first mover in MLIA (after all “World-Wide” is the Web's first name!), but there too adoption has been slower than the technology base would support. One commonly cited limiting factor for Web search engines has been the challenge of developing a suitable business model for monetizing MLIA. Regardless of the cause, it seems clear that developing a broader experience base with MLIA techniques will be an important next step.

In May, 2007, Google introduced a rudimentary MLIA capability by coupling query translation (to search Web pages in a different language) with document translation (to translate the result list, and individual results). Such an approach can be easily “bolted on” to any Web search engine since Web search engines typically already include automatic language identification and language-specific processing. (Indeed, Yahoo announced a similar service for German users in 2005, although apparently without much success.) Similar techniques have been used for CLIR research by modifying freely available information retrieval systems that had originally been designed for monolingual applications (e.g., Lucene), and at least one freely available system includes provisions for easily incorporating translation probabilities (Indri's “weighted structured queries”). Some degree of adoption is now also becoming evident among commercial providers of search services. For example, Autonomy now offers cross-language search capabilities (e.g., for enterprise search by multinational corporations).

These emerging capabilities are first steps in the direction of developing a richly multilingual information ecology that could support the next generation of research on information-seeking behavior in such settings. The few studies that have been conducted in recent years have typically focused on single information systems, relatively narrowly scoped collections, and, of necessity, users who have no prior experience with any MLIA application. As more users gain access to a broader range of increasingly capable systems, richer and more nuanced study designs will become possible.

Some open issues remain with regard to the technology base as well. For example, development costs for language-specific processing depend on the number of languages that must be accommodated, but the overall value of processing a specific language varies with the importance to the user of the languages that might be written in that document. With hundreds of written languages in use around the world, a point of diminishing returns may be reached beyond which the development costs for language-specific processing can no longer be justified. In such cases, a simple alternative is to count character sequences (in the same way as for language identification) and then simply index those character sequences. While this works reasonably well for monolingual applications in

which the query and the document are written in the same language, how best to integrate translation capabilities into such an architecture is presently less clear.

Another open research question in MLIA is how best to present results from different languages. The challenge in this case arises because present systems for ranking documents in decreasing order of probable utility rely on relative relevance" scores that lack an absolute meaning. The consequence is that we can reasonably hope to determine whether one French document is a better match to the query than another French document, but determining whether an English document is a better match to that query than some French document requires that we create some way of comparing English scores with French scores. Progress on this problem has to date been rather disappointing, with merged result lists often being far less satisfactory than the best single-language result set. Presenting several ranked lists, one per language, is possible, but that approach does not scale well as the number of languages grows.

Result set presentation is a special case of the more general issue of interaction design, for which the research to date has just started to scratch the surface. When first introduced, things that are new are often patterned on things that are already well understood. Newspapers, for example, initially resembled the pamphlets that had preceded them. Later, when newspapers first started providing content on the Web, it resembled a printed newspaper. So it should be no surprise that Google's first try at MLIA looks like, well, Google. New capabilities tend to create their own dynamics, however, with new users bringing new needs, which drives development of new technologies, sometimes ultimately resulting in something that would have been difficult to imagine at the outset. MLIA has progressed far enough at this point for us to begin on that path, but not nearly far enough for us to yet predict where that path will lead us.

Museum Accreditation Program

Leah Arroyo
Julie Hart

American Association of Museums, Washington, District of Columbia, U.S.A.

Abstract

For nearly 40 years, the American Association of Museums' Accreditation Program has formally recognized museums' commitment to excellence, public accountability, high professional standards, and continued institutional improvement. Accreditation serves as the museum field's quality assurance and self-regulation.

The Museum Accreditation Program of the American Association of Museums (AAM) formally recognizes museums' commitment to excellence, accountability, high professional standards, and continued institutional improvement. Its purpose is to strengthen individual museums and the entire profession by promoting ethical and professional practices in individual museums and the museum community. Accreditation serves as the field's primary vehicle for quality assurance and self-regulation.

The program assesses how well each museum achieves its stated mission and goals and meets the standards and best practices generally accepted in the museum field. It employs a standardized process of self-study and peer review that incorporates multiple perspectives to ensure balance and fairness. This process draws on the collective wisdom of the field, gathered from participating museums, peer reviewers and the Accreditation Commission, a nine-member, independent and autonomous body that administers the program, and renders all decisions regarding accredited status.

Accreditation offers the following benefits: it certifies that a museum meets the Characteristics of an Accreditable Museum as set forth by the Accreditation Commission, certifies that it has undergone a rigorous process of self-assessment as well as review by its peers, signifies that the museum fulfills its obligations to the public as set forth in its mission and recognizes the institution's commitment to excellence, accountability, high professional standards, and continued improvement.

The accreditation program reflects the diversity of the museum field, accommodating museums' variety in disciplines, from art centers to zoos; budget sizes, from less than \$100,000 to \$150 million and above; governance types—private, nonprofit, or public—and collecting status, including museums that do not own collections.

After submitting an application, a museum spends a year completing a self-study questionnaire. With Accreditation Commission approval, two peer reviewers conduct a site visit and submit a report, after which the

commission votes on accreditation. Peer reviewers are selected from comparable institutions, but with differing areas of expertise targeted for the museum undergoing accreditation. Museums already accredited undergo a subsequent review, or reaccreditation, every 10 years.

In June 1971, 16 museums became the first to be granted accreditation by the AAM. This was a milestone in a process that had begun in 1906, when museum directors came together at the American Museum of Natural History in New York to found AAM and initiate what has become a century-long discussion about developing museum standards and measuring museum performance. Plans for museum accreditation began in earnest in 1967, when President Lyndon B. Johnson asked the U.S. Federal Council on the Arts and Humanities to study the status of American museums and recommend ways to support and strengthen them.

The council enlisted AAM's assistance, and in 1968 the association established a committee to study the idea of an accreditation program for museums. Based on AAM's input, on November 25, 1968, the council issued "America's Museums: The Belmont Report," which stated: "it is urgent that the American Association of Museums and its member institutions develop and agree upon acceptable criteria and methods of accrediting museums." One year later, AAM authorized the Accreditation Committee to define the methods for establishing a program. On June 4, 1970, the committee presented "Museum Accreditation: A Report to the Profession," which outlined the basic principles and framework for AAM's museum accreditation program. Only at that time were the first applications accepted.

Over the years the program has been refined, emphasizing different issues that reflect the issues current to the museum profession: education and program evaluation (1980s), collection management (1990s), and ethics (2000s). Starting in 1986, museums have had to produce collections management policies. In 1996, AAM issued *Characteristics of an Accreditable Museum*, and the

following year an institutional code of ethics was required of any museum seeking accreditation. In 2005, AAM revised its standards, self-study questionnaire, and eligibility criteria. See the AAM Web site: <http://www.aam-us.org/museumresources/accred/index.cfm>.

Accreditation review is voluntary; museums can apply or withdraw at any time. The process is collaborative,

involving a dialogue among a museum's staff, governing authority and program staff; the peer reviewers; and the Accreditation Commission. It is also confidential; information provided by museums, and all correspondence and reports, is shared only with program staff, peer reviewers, and the commission.

Museum Architecture and Gallery Design

Volker M. Welter

Department of the History of Art and Architecture, University of California, Santa Barbara, Santa Barbara, California, U.S.A.

Abstract

This entry reviews the history of the architecture of museum buildings in the Western world (Europe and the United States) where the museum as an institution originated. After a brief history of the institution, chronological sections are dedicated to the pre-eighteenth century when the gallery as a room type emerged in France and Italy, the eighteenth century during which basic architectural and spatial requirements of museums were begun to be worked out, the nineteenth century when the museum as a building type was developed, and the twentieth century and beyond when initially modernist museums rejected the nineteenth-century ideal types and at the turn to the current century eclectic and unique architectural designs, so-called signature buildings, became synonymous with museum architecture.

The museum as a distinct building type developed in such European countries as, for example, France, Germany, Italy, Spain, and the United Kingdom, as well, from the eighteenth century onwards, in countries outside Europe. The museum offers spaces for the assembly, display, study, appreciation, and storage of both natural and man-made objects. Typically, the former are taken out of their natural context whereas the latter are removed from their original purpose, either by chance or deliberation, respectively have never been put to any intended use. Again other objects, ranging from works of arts to dioramas, for example, are created specifically for a museum setting.

Historically, the museum derived from institutions of knowledge generation and learning. Architecturally, it stems from the former and also from spaces that housed collections of objects and artifacts. Accordingly, a museum accommodates the functions and activities of collecting, ordering, exhibiting, and commemorating, each determining aspects of its architecture. Over the course of time the form of the museum as an institution changed as its purpose broadened from being a private place of studying and learning to one that displayed objects amassed in the pursuit of wealth or expert scholarship to becoming a public institution visited by both experts and the general public for aesthetic enjoyment and educational purposes.

HISTORY OF THE INSTITUTION

Etymologically, the word museum stems from the Greek word *museion* which referred both to places of mythological religious worship and institutions of learning. The former were dedicated to the nine muses, goddesses and children of Zeus and Mnemosyne, the goddess of memory.^[1] Such places of worship, with or without a shrine, were typically set in nature like, for example, on a hill

called *museion*, opposite of the Acropolis in Athens, on Mount Helicon, on Mount Parnassus, and at Pieria below Mount Olympus, the birth place of the muses. The ancient Greek word also referred to institutions of learning and knowledge such as, for example, the *museion* in Alexandria that was established in the third century B.C. for scholars of the local academy.^[2]

Regardless of this shift in the meaning of the word “from the religious and ethical to the intellectual,”^[3] both types encouraged the contemplative withdrawal into the realms of either pastoral nature or a study. Spatially, the former was unconfined, whereas the latter was locatable in two ways. First, as an institution that surveyed and ordered the cultural resources of the city or society of which it was part; second, and more specifically, as the physical space where learning took place.^[4] Thus, the museum as “simultaneously an open and a closed concept” (p. 62)^[4] determined the development of the institution.

When pondering the universe a medieval scholar may have retreated, for example, into a studio (study). Comparably, *Kunstschrank* (studiolo or art cabinet), *Wunderkammer* (curiosity cabinet), and library accommodated for scholarly study collections of typical, rare, and unique objects and artifacts. These spaces became increasingly popular when during the sixteenth century taxonomy and classification emerged as strategies to grasp a world that, from the European point of view, expanded rapidly due to increased overseas trade and political, later also colonial and imperial, relationships with countries on other continents. Often located in domestic buildings, rooms for collections mediated between the world and the home, the public and the private (p. 69).^[4]

By the beginning of the seventeenth century the museum had moved from the studio to the galleria, “a space through which one passed, in contrast to the static principle of the spatially closed study” (p. 69).^[4] The

galleria as a room in which to display a large numbers of objects marked an important beginning of the museum as a distinct building type.

During the eighteenth century foundations of the early modern museum were laid with its twofold emphasis on an educational function and the aesthetic appreciation of the exhibits. The art historian Ernst Gombrich (1909–2001), for example, identified *prodesse* and *delectare*, to “profit and delight,”^[5] as the two main tasks of the early modern museum. The modern museum emerged when two earlier types of display, the treasure and the shrine, combined to form “the depository and the didactic display” (p. 456).^[5] The treasure, for example, royal collections, bolstered the social standing of the owner by overwhelming visitors with a wealth of objects (p. 452),^[5] whereas the shrine exhibited selectively objects that were “not simply rare but unique” (p. 453).^[5] When such collections were increasingly opened to the public, the treasure was transformed into a depository of “specimens to illustrate the rise of the arts” while the unique objects in the shrine now illustrated the end point of a “road to perfection” (p. 456).^[5] In short, the formation of a canon of Western art was decisive for the concept of the modern museum.

From the nineteenth century onwards, the museum became not only more visible within the public realm of the modern city but was increasingly accessible to the public at large, even if it was not always held in public, for example, municipal ownership. The latter was, in the twentieth century, often seen as a direct expression of the social function of the museum. For example, the museologist Alma S. Wittlin (1899–1990) argued in the mid-twentieth century for a shift away from the museum as an expert institution that was also accessible to an educated public towards an educational experience geared primarily at the general public. Wittlin stressed that the modern public museum should value, both primarily and equally, the two tasks of providing enjoyment and education.^[3]

Since its inception, the modern museum has oscillated between a didactic exhibition dictated by a canon or any other story and the display of exhibits for pure aesthetic contemplation. In the early twentieth century, many museums began to widen their purpose with public and educational outreach programs, which by the latter part of the century were complemented with entertainment oriented towards consumers and donors alike, and other events in an attempt to alleviate shortfalls in, especially, public funding and to counter charges of elitism. Nevertheless, museums are even today often surrounded by an aura of the extraordinary. This is not only expected by many visitors and donors, but is the tangible result of the “conflicting demands of the civic and hermetic notions” (p. 71)^[4] of the museum. The latter two have determined the historic development of this essential institution of Western culture and continue to influence concepts of the contemporary museum as it has been adopted worldwide. Museum architecture likewise operates between

potentially conflicting expectations. On the one hand, it should serve the museum as an institution that is dedicated to the exhibition and preservation of the objects in its custody. On the other hand, architects often wish to inscribe into the urban fabric with strong and powerful architectural images the importance of the museum as a civic institution.

HISTORY OF THE BUILDING TYPE

The double roots of the museum in collections of objects and in institutions of learning and knowledge have determined the development of museum architecture. From the former derived the gallery, a typical exhibition room of a museum, whereas the latter influenced the development of the general building type. Museum architecture touches primarily on solutions regarding the display of objects, the organization of exhibitions spaces and the increasingly complex functions of a museum, and the relation of the museum building to the wider built environment. Changing architectural styles were not always of great influence on the development of the building type. Similarly, while the foundation of national and other large museums were crucial for the history of the institution, their architecture was not necessarily of equal importance.

Pre-eighteenth Century

Already European antiquity knew of spaces dedicated to art works like the pinacotheca on the Acropolis in ancient Athens where paintings were displayed in order to honor the gods. Both Vitruvius (fl. later first century B.C) in the *Ten Books on Architecture* and Pliny the Elder (A.D 23 or A.D 24–79) in his *Natural History* referred to spaces like, for example, arcaded perambulatories that also accommodated sculptures or mural paintings.^[6] Vitruvius explained that because of their at times considerable length such spaces were often decorated with landscape murals and sculptures. Moreover, they were reserved for the domestic architecture of dignitaries with civic obligations, thus the art works were part of a decorative iconographical program focusing on the owner of the house.

During the Renaissance art was begun to be looked at, and accordingly collected, as art. One of the earliest examples of an architectural space created specifically for art exhibits was the Belvedere statue court (Cortile delle Statue) that the architect Donato Bramante (1443 or 1444–1514) designed for the Vatican during the papacy of Julius II (1503–1513).^[7] Located to the north of the Belvedere courtyard (Giardino della Pigna), statues were accommodated in niches along the perimeter walls, among them the famous Laocoön group that had been found in Rome in 1506. That the latter was placed in a direct sightline with the adjacent Belvedere Villa may indicate that one goal was to achieve the best possible display of

the sculptures (p. 66).^[7] While still open to the elements, the court was a marked improvement over the prevailing outdoor displays of ancient sculptures in gardens, loggias, and on terraces.^[8,9]

With centrally planned rooms and arcades like perambulatories, Antiquity furnished Renaissance architects with two types of spaces upon which rooms for sculptures and other works of art could be modeled. The top-lit, domed rotunda of the Hadrianic Pantheon (ca. A.D. 118–125) in ancient Rome was one model to which museum architects resorted time and again. It probably inspired the circular and top-lit building of the painter Peter Paul Rubens (1577–1640) in Antwerp where his collection of ancient sculptures was displayed (p. 112).^[8,9]

Arcaded spaces were evoked in the gallery, a room type of lasting importance for museum architecture. Nowadays, the word refers either to a separate room for a defined group of objects, or to a building dedicated to a class of objects or temporary exhibitions of, for example, contemporary art. Historically, the word gallery referenced a type of room, more long than wide, that in its modern appearance originated in France.^[10] Initially functioning as entrance halls and connecting corridors, galleries were used from the mid-fifteenth century onwards to accommodate collections of, for example, antlers, natural objects, or paintings (see appendix: Verzeichnis der im Text besprochenen Galerien).^[10] While they derived from ancient arcaded perambulatories as described by Vitruvius, they were enclosed to better suit the northern European climate. Ideally, they were lit by windows on both long sides, but where that was impossible landscape paintings substituted for the view of the surrounding environment.

Galleries developed into a standard element of European palace architecture, but it was in Italy from the sixteenth century onwards that they were also begun to be used for sculptures and paintings, not least due to the excellent provision of light between and opposite the exhibits (p. 3).^[3] A prominent example is the nearly 300 ft long gallery in Sabionetta designed ca. 1583–1584 by the Italian architect Vincenzo Scamozzi (1548–1616). It was initially decorated with frescoes of mercenaries, then redecorated with a collection of antlers, celebrating the hunting privilege of the owner, and finally used to exhibit a collection of ancient statues (p. 52).^[10] The Antiquarium in Munich was commissioned by Albert (Albrecht) V of Bavaria (1528–1579) for his sculpture collection.^[11] The tunnel-vaulted gallery that was rebuilt after its destruction in World War II was designed between 1569 and 1571 by Jacopo Strada (1515–1588), built to a plan amended by Bernhard and Simon Zwitzel, assisted by Wilhelm Egckl (ca. 1520–1588), and from 1586 onwards decorated by Friedrich Sustis (ca. 1540–ca. 1599) (p. 103).^[8] It was located on the ground floor of the new building with the library of Albert V on the upper level. Both these examples illustrate that works of art or any other exhibit displayed in these early galleries were typically integrated

into a decorative program whose iconography aimed at glorifying the gallery's owner (p. 60).^[10]

The conceptual origin of the museum in places of learning and knowledge influenced the beginnings of a distinct building type for the institution. Latest from the sixteenth century onwards contacts of European societies with those on other continents and an increasing awareness of the material heritage of earlier periods of European history resulted in a fascination with collecting unique, rare, and unusual objects and artifacts. Wunderkammern (curiosity cabinets) and Kunstkammern (art cabinets) encapsulated in visible and tangible form the known universe in order to allow scientific inquiry and study.^[12] One of the earliest purpose-designed buildings for a collection of this kind was Albert V's new Marstall in Munich which also housed the Kunstkammer. Shortly before he worked on the Antiquarium, discussed above, Egckl had built in 1563–1567 this new edifice (later the Alte Münze) around an open quadrangle with arcaded, open corridors that gave access to the rooms on each level. The art chamber's content was displayed on tables, in cupboards, and hung from the walls in large galleries that stretched around the courtyard on the third level. Rooms for valuable objects were separated in the corners of the quadrangle.^[13,14]

Possibly the world's oldest, purpose-designed public museum building was begun in 1679 and opened in 1683 in Oxford, England, for the Ashmolean museum; today it accommodates the Museum of the History of Science. The museum's origin was a universal collection of natural objects and artifacts that Elias Ashmole (1617–1692), an antiquarian, had donated to the University of Oxford after it had originally been amassed by the naturalist John Tradescant, the older (1590–1638), and his son. Installed on the top floor of the new building, the display was supplemented with a lecture room on the ground floor and laboratories in the basement. The building, whose design has been ascribed to either Thomas Wood (1664 or 1665–1695) or Christopher Wren (1632–1723),^[15] is of oblong, rectangular shape which ensured gallery proportions for the exhibition space.

Eighteenth Century

At the outset of the eighteenth century one of the earliest architectural plans for a new museum known to us was published in a 1704 essay on an ideal "rarity chamber" for a universal collection of art, curiosities, and natural objects.^[16] Art historians have ascribed the pamphlet to the scholar and architect Leonhard Christoph Sturm (1669–1719) (p. 104),^[8] (p. 114).^[9,17] More recently it has been ascribed to Paul Jacob Marperger (1656–1730).^[18] This pamphlet stands in the tradition of writings about curiosity cabinets, art cabinets, and museums that, in the case of the German-speaking countries, for example, stretches back to the 1565 publication *Inscriptiones vel tituli teatri amplissimi* by Samuel van Quiccheberg

(1529–1567); a book written in close connection with the establishment of the *Kunstkammer* in Munich (p. 336).^[17,19] The 1704 essay was illustrated with a plan that showed the ground floor of a three-storey, rectangular building surrounded by a botanical garden, an orangery with foreign plants, and a small zoo of foreign animals. The design of the museum is one of the earliest that assigned separate rooms to different classes of exhibits instead of mixing them in one gallery (p. 114).^[9] The relation between exhibition spaces and exhibits was also addressed by recommending a restrained interior decoration that would not conflict with the exhibits. The character of the objects should determine the display which should follow the principles of conservation, good visibility, scientific order, and aesthetic effect (pp. 336–338).^[17]

Other ideal museum designs followed. In 1759, Count Francesco Algarotti (1712–1764) described a proposed new museum for Saxony as “a square building with a large courtyard and in each range a Corinthian loggia and one room on either side of it. These eight galleries lead into four corner rooms, each lit by a small dome. A large dome is above the centre of each range lighting the principle room behind the loggia (p. 104).”^[8]

The scheme combined galleries along the four sides of a courtyard, each of them divided into two separate units by centrally located rooms. The latter were modeled on the Roman Pantheon and accessible through a columned portico or “Corinthian loggia” as the count had called them (p. 114).^[9]

This courtyard plan was for a long time a favorite model for ideal museum designs. A variation inscribed into the larger square a Greek cross with a central room at the crossing of the four arms which, in turn, lead to the circumferential galleries and thus creating four smaller courtyards within the larger quadrangle. This addition increased both gallery space and rooms to accommodate different museums and related institutions like libraries in a single building. For example, the designs with which Jacques-Pierre Gisors (1755–1818) and François-Jacques Delannoy (1755–1835) won in 1778–1779 the Prix de Rome competitions of the French Académie d’Architecture followed this model. Likewise, Étienne-Louis Boullée (1728–1799) designed an ideal museum in 1783 that adopted the basic pattern of a Greek cross inscribed into a square. Envisioned as a multifunctional institution including an art museum, a natural history museum, a print room, a library, and a national monument with statues of French heroes underneath the central dome, the boldness of Boullée’s undecorated architecture and its gargantuan size has proved attractive to many architects ever since. Jean-Nicolas-Louis Durand (1760–1834), another French architect, developed this type of ideal museum into a more practical solution. His *Précis des leçons d’architecture* (1802–1805) included a general design for a museum that was adaptable in size and exact configuration to varying circumstances.^[20]

Throughout the eighteenth century important architectural developments also happened on the smaller scale of exhibition spaces and galleries, especially with regard to, first, the relationship between the conceptual order of the displayed objects and the spatial order of the exhibitions rooms, and, second, the architectural settings of exhibits within individual rooms. The first point arose because the integration of objects into decorative schemes may have become overlaid with conceptually ordered displays that emphasized, for example, thematic, formal, and aesthetic principles. The exhibition of sculptures in the gallery spaces of the Villa Albani in Rome, commissioned by Cardinal Alessandro Albani (1692–1779) in the 1740s and completed in the 1760s to a design by architect Carlo Marchionni (1702–1786), was organized along iconographic-thematic principles. These were conceived by art historian Johann Joachim Winckelmann (1717–1768) who grouped together sculptures of the same subject matter (p. 114).^[9] Thus the architectural divisions of the exhibition spaces into a sequence of larger and smaller rooms acquired a new importance as the thematic groups of exhibits occupied separate spaces. Beside the art historical logic of such displays, the architecturally interesting issue is the relationship between the spatial sequence of rooms in a gallery or a museum, and the ideal order—formal, aesthetic, thematic and, later, chronological,—in which the exhibits were displayed and, presumably, to be viewed. The plans of the gallery (1767–ca. 1780) at Newby Hall, Yorkshire, England, and of the Museo Pio-Clementino (from 1770 onwards) at the Vatican are exemplary illustrations of this important architectural-museological issue. Both buildings are of vast difference in scale, the English gallery being an annex to a private house whereas the Roman example was an instrument of Papal power with regard to size and ambitions. Nevertheless, architecturally speaking, both buildings center on a circular room in which important exhibits were shown.

Newby Hall’s gallery stands in the tradition of small, private art galleries, a distinct British contribution to museum architecture.^[21] The architect Robert Adam (1728–1792) extended the main house with a gallery for antique sculptures. The focus was a Pantheon-like rotunda—similar to a circular top-lit sculpture gallery Adam had designed for Kedleston Hall (1758–1763), Derbyshire, England—that was flanked at either side by a square room, a symmetrical arrangement that made the circular room to the center of the plan while the small size of the entire extension kept subtle this hierarchy.

This was different in the case of the Museo Pio-Clementino that was added to the Vatican by the architects Michelangelo Simonetti (1724–1787) and, later, Giuseppe Camporesi (1763–1822). To the irregular site the architects responded with a series of spaces, each of a distinct geometric form like, for example, a Greek cross, a rotunda, a hexagon, squares, and rectangles, that wrapped around the east, north, and west side of the Belvedere

sculpture court. The new range was originally entered at the north-west corner of the Belvedere courtyard (Giardino della Pigna). From there visitors moved upwards on a grand staircase, built to a design by Simonetti, and towards one of the most impressive rooms of the new museum, the rotunda where sculptures of deities were exhibited. All other art works were arranged thematically in the following galleries. Because the museum was a linear, though irregular sequence of rooms, the conceptual relationship between the latter and the exhibits was both a curatorial and an architectural issue. For example, with the addition of the new galleries, the Belvedere statue court, that had also been remodeled by Simonetti in 1773, was now located at the end of the concourse, accordingly it could be considered either as the highlight of the museum or as its appendix.

The Museo Pio-Clementino was also remarkable for the period design of the interior of the galleries whose neoclassical style alluded to a unity between the ancient exhibits and their contemporary architectural setting. The latter aimed at evoking broadly classical antiquity including original antique Roman mosaics on the floor of, for example, the Rotunda room. A comparable idea of a period setting for exhibits also determined the short-lived Musée des Monuments Français that existed from 1796 until 1816. There the painter Alexandre(-Marie) Lenoir (1762–1839) amassed medieval funeral monuments and other, mainly religious objects that were displayed in a chronological order in a thirteenth-century monastery in Paris.^[8] In this case the exhibition spaces were not consciously designed as period rooms but were in a building from the same period as many of the exhibits; thus the latter and the architectural setting interacted particularly closely with each other.

During the eighteenth century some of Europe's best-known museums were founded, some in existing buildings, others in newly erected ones. The Musei Capitolini in Rome was opened to the public in 1735, followed by the Galleria degli Uffizi in Florence in 1743, though the origins of both museums go back much further. The British Museum, the world's first publicly owned museum, was founded in 1753 by an act of Parliament that acquired for the nation the collection of Hans Sloane (1660–1753) that comprised both objects that illustrated natural history and artificialia. The museum opened in Montagu House, a seventeenth-century manor house in Bloomsbury, London, in 1759. In Vienna the Kaiserliche Gemäldegalerie was established in the Upper Belvedere palace (1717–1724) designed by Johann Lukas von Hildebrandt (1668–1745) in 1781. Before that some of the paintings had been displayed in the adapted Stallburg, a stable from before the mid-seventeenth century.^[22]

The Louvre in Paris that opened in 1793, occupied a royal palace whose origin stretched back to the twelfth century. Already during the seventeenth century works of arts were shown in the Louvre, for example, the Académie

Royale de Peinture et de Sculpture's annual exhibition in the Grande Galerie that had been built between 1595 and 1610 as a connecting corridor. From the mid-eighteenth century onwards these shows were located in the Salon Carré. These two spaces became the germ cells of the Louvre when it was reconceived towards the end of the eighteenth century as the nation's premier museum for works of art. Architecturally, the Louvre is an example of a palace adapted to its new purpose, but regardless, the interior of its galleries influenced many later museums. Already in 1789 top lighting had been installed in the Salon Carré, arguably one of the best light provisions for picture galleries. The painter Hubert Robert (1733–1808) depicted in 1796 also the Grande Galerie with skylights, a proposal that was possibly derived from a ceiling design in a Boullée design for a national library (1784). The gallery, however, had to rely on high sidelighting until 1938 (p. 109).^[8] A new grand staircase leading to the galleries and the neoclassical redecoration (1805–1810) of the Grande Galerie by the architects Charles Percier(-Bassant) (1764–1838) and Pierre-François-Léonard Fontaine (1762–1853) were probably inspired by the Museo Pio-Clementino.

New museum buildings were, for example, erected in St. Petersburg, Russia, in Kassel, Landgraviate of Hesse-Kassel, Germany, and in Madrid, Spain. The Kunstkamera (1718–1734) in St. Petersburg housed both Peter the Great's royal collections of natural and artificial objects, and the library of the Academy of Science.^[23–25] The Baroque design by the architect Georg Johann Mattarnov (died 1719) consisted of two oblong, three-storey tall wings to either side of a tower. At the far ends smaller rooms were located followed by galleries in the eastern wing and the library in the western one. The central tower accommodated an anatomical lecture theater and observatories that included a wooden globe (Germany, sixteenth century) with a painted map of the world on the outside and one of the firmaments on the inside. Conceptually, the Kunstkamera stood still in the tradition of curiosity cabinets.

This was also the case in Kassel where the enlightened ruler Landgrave Frederick II (1720–1785) commissioned the Museum Fridericianum (1769–1779), one of the earliest purpose-designed public museum buildings in continental Europe. It combined art galleries with ones exhibiting artifacts, including cork models of famous buildings, and a library.^[26] The architect was Simon Louis du Ry (1726–1796). Today, this museum is best known as one of the venues of Documenta, the international exhibition of contemporary art.

In 1785, Juan de Villanueva (1739–1811) began to design a new natural history museum in Madrid which, before its inauguration in 1819, was already rededicated as art museum and later named Museo Nacional del Prado. The neoclassical design is based on an additive architectural design principle whereby suitable geometric forms

are selected according to the different functions of various rooms and then brought together in a formal overall composition much like, for example, Durand's schematic museum design. In Madrid, a long, narrow gallery spans between two square end pavilions that is bisected in the center by a perpendicular gallery. The main entrance was in one of the end pavilions from where visitors passed through a skylit circular rotunda. The museums in St. Petersburg, Kassel, and Madrid were physically separated from the palaces of their founders thus making visible their foundation in ideas of the Enlightenment, even though they all were of royal, imperial, or courtly origin.

This was different in the case of museums outside Europe that began to be established in the eighteenth century. Often, they were part of exploratory or colonizing efforts. For example, in North America one of the earliest collections of plant specimen and natural objects was founded by the Charleston Library Society, South Carolina in 1773,^[27,28] obviously driven by the wish to become familiar with the flora and fauna of the new continent. Other museums were part of the attempts to establish a new society by transplanting elements of the European ones. That museums like, for example, the American Museum in Philadelphia—founded from scratch by Pierre Eugene du Simitière (1737–1784) in 1782 and sold upon his death (p. 7)^[28]—were considered to be part of the new society speaks about their popularity. Purpose-designed buildings were apparently erected only in the next century when, for example, the Pennsylvania Academy of the Fine Arts in Philadelphia occupied in 1806 new premises in which a collection of plaster casts was exhibited. The brick cube with a shallow dome, slightly protruding corners, and a door way above which a carved American eagle hovered was designed by John Dorsey (ca. 1759–1821) in a Federal style.^[29]

Nineteenth Century

While during the eighteenth century the architectural basics of the museum as a distinct building type were developed, the next century saw their perfection and widespread application.

Architecturally, the century began with three buildings that inspired museum architecture for years to come: the Glyptothek (1816–1830, restored 1972), a sculpture gallery, and the (Alte) Pinakothek (1825–1836, restored 1945), a painting gallery, both in Munich, Bavaria, to designs by Leo von Klenze (1784–1864), and the (Altes) Museum (1823–1830, restored 1960s, sculptures and paintings) in Berlin by Karl Friedrich Schinkel (1781–1841). The Glyptothek was characterized by an exceptionally well-conceived unity between architecture and exhibits, and a chronological display that was mirrored architecturally in a rigidly set route through suites of galleries around a courtyard. Period rooms dominated the settings of sculptures that stood, for example, in rows

along walls as to outline the silhouettes while emphasizing the axes of the rooms, were placed as focal points at the end vistas through galleries, or were the center point of individual rooms.

The Altes Museum intertwined skillfully the public realm with the museum space. Schinkel designed a free-standing cube facing the Berlin Stadtschloß (demolished 1950) across the open space of the Lustgarten. A broad stair approaches a screen of double-height columns behind which the entrance is located, a master piece of spatial complexity that, in its original form, led visitors into the building with one flight of steps, took them out again with the next after which the top landing was reached that, from underneath the roof, directed the gaze back towards the city beyond the columns, a view that is now altered by glass panes placed between the columns. Inside, this view was matched by the sublimity of a domed, top-lit, double-height rotunda with a column-supported gallery on which sculptures stood. To either side of this room galleries wrapped around two open courtyards offering strictly sequential routes on each floor.

The Alte Pinakothek revolutionized the spatial organization of galleries. (Fig. 1) The lower floor of the long and narrow building with two slightly protruding end wings was primarily for scholars and offered offices, a library, a print room, and storage space. The publicly accessible upper floor organized circulation spaces and galleries in three parallel bands. A narrow loggia ran from east to west along the southern length of the building. The main band arranged top-lit galleries of slightly different lengths in a rhythm of a-b-a-c-a-b-a that singled out subtly the center-most room. U-shaped cabinets for small paintings opened towards the northern façade in the third band. This arrangement was overlaid with a network of possibly routes that connected axially the galleries with each other in order to mirror in plan the chronological display by schools, while a multitude of north–south links allowed for sudden cross moves, “the spice of museum visits” (p. 138).^[9]

Thus early in the century two principle museum plans were available. One, following Durand's ideal museum plan, organized exhibition spaces around one or two courtyards with usually a central, architecturally highlighted space. The other plan was a long, shallow building, typically with projecting pavilions in the center and at both ends. Both types utilized the compositional Beaux-Arts method and were also influential regarding their architectural styles, usually neoclassical or versions of Renaissance styles which, in turn, had revived Greco-Roman architecture. Moreover, they set standards for a civic monumentality of museum buildings. Often, the latter were elevated by broad flights of stairs leading to main entrances in facades that evoked either ancient temples or palatial edifices as exemplified in the forecourt of the new British Museum (1823–1848) by Robert Smirke (1786–1867).

The two basic types differed regarding land use, expendability, and lighting. The courtyard model made

Fig. 1 Leo von Klenze (1784–1864), floor plans of the lower level (bottom) and upper level (top) of the Alte Pinakothek Munich as inaugurated in 1836. The main entrance is at the right end of the lower level. The upper level shows the division into three parallel bands of exhibition rooms and circulation spaces. **Source:** Photograph courtesy of Bayerische Staatsgemäldesammlungen, Alte Pinakothek Munich, Germany.

efficient use of building plots and adding new courts created more galleries. The free-standing, shallow buildings of the other type assured both good light supply on the long sides of, for example, a painting gallery, and excellent light penetration of the interior. The latter became less important with the increased use of iron and glass lanterns from the eighteenth century onwards. That top lighting was beneficial to display works of arts antiquity already knew. The principle had also been employed to light the niches (*gabinetti*) of the remodeled Belvedere statue court (1773) and in some galleries of the Louvre. The Dulwich Picture Gallery (1811–1814), London, by John Soane (1753–1837), another fine English example of a small art gallery, and the Pinakothek, that proudly displayed lanterns on the roof, were successful modern applications of roof lanterns to exhibition spaces. Until then, galleries had mainly been lit through conventional windows or clerestory windows that provided diagonal light from high above.^[30]

At the beginning of the century, only very few European cities like, for example, London, Paris, Rome, and Vienna, were the location of important, even national, museums. By the end of the century, the number of museums had multiplied as the example of the United Kingdom shows. To the 59 museums that existed in 1850, 259 more had been added by 1914 (p. 136).^[31] Museums were also established on continents and in countries that were in contact with or colonized by Western powers like, for example, India (Indian Museum, Kolkata, 1814, whose origin goes back to the Asiatic Society of Bengal from 1784), Brazil, (Royal School of Fine Arts, today Escola Nacional de Belas Artes, Rio de Janeiro, 1816, that exhibited a painting collection),

and Japan (Museum of the Ministry of Education, today the Tokyo National Museum, 1872).

Architecturally consequential was the adaptation of museum buildings to three developments—growth, specialization, and spatial concentration—that affected museums during the later century. Individual museums grew because with the adoption of didactic displays, chronological or thematic, the need to expand arose as any conceptual order could always be made more comprehensive if allegedly existing gaps in a collection were filled (p. 457).^[5] As a response to this growth but also to the increasing separation of individual disciplines in the sciences and the humanities, many museums began to specialize by focusing on select classes of objects. Museums exhibiting together natural objects and man-made artifacts continued to exist, although often older universal collection were dissolved as the dispersal of the Danish Royal Kunstkammer (1650) between ten different museums shows.^[31] Regardless, the museum complex, a spatial concentration of different types of museums in the immediate vicinity of each other, gave new spatial form to the idea of a universal collection.

A prime example of these interconnected developments is the Victoria and Albert Museum in London, one of the many museums established from mid-century onwards that were dedicated to the applied arts, their role in modern production, and their relationships with the sciences.^[32] A predecessor was the Parisian Hôtel de Cluny that had opened in 1843 with an exhibition of Medieval and Renaissance everyday objects in historicizing settings. Rooted in the contemporary debate about the relationship of the arts and the sciences in an age of capitalism, one goal of these museums was the education of artisans, workers, and citizens in the aesthetics and production of modern commodities. Today's Victoria and Albert Museum was founded as the Museum of Manufactures the year after the 1851 Great Exhibition of the Works of Industry of All Nations in London, opened on its current site as the South Kensington Museum in 1857, and received its current name in 1899. From its inception onwards, the museum was closely allied with a government-initiated school of design.

The museum's early architectural history was intertwined with the rise of iron as a new structural material. Initially, the museum occupied a prefabricated structure, clad with corrugated metal, whose iron and glass roof hovered visibly over the interior spaces. This utilitarian building was elevated to architecture proper in 1862 by two iron and glass exhibition courts that borrowed from church buildings their internal arrangements of central naves flanked by side naves. Another possible source was the iron and glass structure that covered the exhibition court of the new Oxford University Museum (begun 1855), completed 2 years earlier by the architects Thomas (Newenham) Deane (1828–1899) and Benjamin Woodward (1816–1861).^[33] In Oxford, the iron structure was

integrated into a Victorian Gothic building, in London it was designed in a northern Italian Renaissance style.

This pointed towards a second aspect of the Victoria and Albert museum's architecture viz. that it was a sequence of increasingly formal buildings. The next extension from 1869, another Italianate design by the engineer Francis Fowke (1823–1865), added traditional elements of museum architecture such as, for example, an open courtyard and a temple-like entrance pavilion that included one of the first refreshment rooms ever installed in a museum.

The architecture of this type of museum was integral to its educational mission. In the Oxford University Museum, that hosted science departments, ornaments on structural details were derived from plant forms and shafts of columns were hewn from various British stones. In London, the exterior featured artistically designed terracotta panels, and the interior, for example, mosaics portraying famous artists and murals by Frederic Leighton (1830–1896) depicting the industrial arts at times of war and peace.^[34] Instructive decorations had long been a feature of contemporary museum buildings. For example, in the loggia of the Munich Pinakothek murals by Peter (Joseph) von Cornelius (1783–1867) presented the history of painting as a preparation for the true art inside the galleries. In museums of applied art and sciences such details matured from decoration to practical demonstrations of contemporary skills and proclamations of the anticipated merger of arts and sciences. The envisioned renewal of this cooperation was not confined to the small scale of symbolic architectural details, but was also made visible with the museum complex on the larger scale of the modern metropolis.

Specialization did not reject the universal museum as a means to both explore and interpret the world (p. 61).^[4] Rather, this idea shifted to a spatial concentration of different museums and educational institutions in the immediate vicinity of each other. In London, the Victoria and Albert Museum was complemented by the Museum of Natural History and the Science Museum. The former was an offspring of the British Museum, housed in a German-Romanesque building (1872–1881) by Alfred Waterhouse (1830–1905). The latter had originally been part of the Victoria and Albert Museum, but was separated in 1909 when the older museum expanded into a new building (1899–1909) by Aston Webb (1849–1930) (p. 131).^[9] This cluster in South Kensington comprised also teaching and bibliographical institutions like, for example, the Royal School of Mines, founded in 1851, and the Imperial Institute from 1887, an information brokerage on and for the British Empire. Comparable clusters were formed in other cities. In Vienna, the Naturhistorische Museum (1871–1889) and the Kunsthistorische Museum (1871–1891), both designs by Gottfried Semper (1803–1879) and Carl von Hasenauer (1833–94), faced each other in front of the Hofburg in a symbolic juxtaposition of the arts and nature, respectively, natural sciences. In Berlin, the museum island, a concentration of mainly

art museums to the north of the Altes Museum, originated in the idea of Friedrich Wilhelm IV of Prussia (1795–1861) to establish a centre of the arts and the sciences that encompassed the neighboring university founded by Wilhelm von Humboldt (1767–1835) in 1810.

Clusters of museums and educational institutions were also an important element of town planning and planned urban expansion. In 1847, Benjamin Disraeli demanded that vast cities like London needed a forum or Acropolis of cultural institutions that would ennoble “the metropolitan mass.”^[35] This was echoed, with a different pitch, in the early 1880s by Thomas Cogan Horsfall (1844–1932), director of his own Manchester Art Museum (1877–1953), who proposed to bring with art museums beauty to urban quarters, especially to working class areas.^[36] This town planning aspect stretched back in modern times at least to the eighteenth-century Museum Fridericianum that stood proudly on a new public square in Kassel. The grounds for the new Glyptothek and the new Pinakothek in Munich had been outside the city limits, while the South Kensington Museum on the edge of London initiated calls for cheap public transport (pp. 29–30).^[32] These contributed to the opening of a station in South Kensington in 1868 by the Metropolitan Railway.

The educational aspect of museums fell on particular fertile ground in the United States where, as already noted, early natural history museums, for example, had a practical role in the settlement efforts. Similarly, the educational and training benefits of art museums were emphasized over collecting art for purely aesthetic enjoyment (p. 37).^[32] Accordingly, many museums were initiated by historical societies, libraries, art schools, and colleges, occasionally in collaboration with a private donor. For example, at Yale College, Newhaven, Connecticut, the Trumbull Gallery was named after architect, artist, and diplomat John Trumbull (1756–1843) who had given the art and designed the Greek Revival style building (1831–1832, destroyed 1901) (p. 24).^[29] After the South Kensington model of art education and training in combination with a museum had become known widely, for example, through the 1876 Centennial Exposition at Philadelphia (p. 38),^[32] comparable museums began to appear in the United States. In Boston, MA, for example, the Museum of Fine Arts that was chartered in 1870 moved into its first building in Copley Square in 1876. The architects, John Hubbard Sturgis (1834–1888) and Charles Brigham (1841–1925) designed a Neo-Gothic brick building (1870–1876, enlarged 1879 and 1890, destroyed) that, while differing in style, took its cues from the London predecessor including, for example, decorative façade panels, instructive interior elements like decorative cast iron stairs, and the installation of entire historic rooms as a backdrop for period exhibits (pp. 29–30).^[32]

Within a matter of years the museum had grown out of its premises and, together with changed ideas about museum display that put greater focus on the aesthetic

aspect of exhibits and collections; this made necessary a move to another site. Even though the new building, a Beaux-Arts design by Guy Lowell (1870–1927), was only begun in 1906, the plan sums up nineteenth-century thinking about museum buildings. The formal forecourt with projecting wings and the classical style speak of the civic monumentality more pronounced than the old building. The master plan evolved around three design principles: The larger building is composed from smaller units, some with their own entrances, for individual departments and collections, a differentiation between levels according to usage with the public galleries on the upper level and services for scholars on the lower—an idea that von Klenze had already introduced in the Munich Pinakothek—and oblique light through windows as the major light source supplemented by skylights (pp. 41–42).^[29]

Twentieth Century and Beyond

The two basic museum types of the nineteenth century never disappeared from the repertoire of possible museum buildings. As late as 1923 the Beaux-Arts inspired plan was considered to be standard.^[37] The National Gallery of Art (1936–1941), Washington, D.C., by John Russell Pope (1873–1937), proved that the oblong, shallow building was also transferable to a different period and tasks. Many early twentieth-century museums were mergers and variations of these two types (pp. 38–41),^[29] though they were faulted for formalism in plan and elevation. For example, the placement of windows according to style rather than to lighting needs was criticized as was the fact that different functions like moving through a gallery and sojourning in front of an exhibit were not separated spatially. Many museum ideas of especially the first half of the twentieth century aimed to overcome such alleged functional deficiencies with contemporary, modernist designs that would also embody the *Zeitgeist*.

With “The Museum of Tomorrow” (1929) the architect and planner Clarence Stein (1882–1975) adapted the museum to American metropolitan architecture by designing a skyscraper that would accommodate better both growing collections and the different needs of scholars and the general public.^[38] Scholarly collections were placed in galleries along the perimeter of the octagonal building, while public galleries spanned across a central courtyard like spokes of a wheel. Different geographical areas and historical periods were assigned to individual floors that, vertically stacked, made the tower expressive of the conceptual order but created also a rigid spatial sequence. A comparable correspondence determined the ideal museum the architect Le Corbusier (Charles-Edouard Jeanneret, 1887–1965) produced in 1929 for the Mundaneum, a world institute of bibliographical information.^[39] A pyramid accommodated a spiral of three parallel naves that wound downwards and symbolized the “chain of knowledge.” Both examples drew on the

Outlook Tower (1895 onwards), Edinburgh, Scotland, of the biologist and city planner Patrick Geddes (1854–1932), a civic museum that embedded local history into widening geographical areas on each lower floor, an idea Geddes had transferred to a design for an outlook tower in a skyscraper when he visited the United States in 1923.^[40]

Stein and Le Corbusier’s ideal museums made visible Modernism’s comprehensive claim to understanding and designing the totality of modern human life; an assumption that was rooted in a progressive view of history as leading inevitably to Modernism. Modernist museum architecture rejected historical models for the building type, but often adopted the spatially fixed, didactic route through an exhibition. The Museum of Modern Art in New York, that was founded in 1929 and moved in 1939 into a new building to a design by Philip L. Godwin (1885–1958) and Edward Durrell Stone (1902–1978), told the birth of Modernism as a chronological sequence of modern art movements, one following the other, similar to the suite of galleries that mirrored this narrative; a spatial dogmatism that was adhered to as late as 1984 when the architect Ieoh Ming Pei (born 1917) expanded the museum. Similarly the Solomon R. Guggenheim Museum (1943–1959) in New York by Frank Lloyd (Lincoln) Wright (1867–1959) where visitors walk down a ramp that circles around a central atrium. Changing exhibitions are mounted in bays along the perimeter wall. Upward- or downward-directed views across the circular space towards other exhibition cabinets are possible, cross moves are not.

The opposite idea of maximum spatial liberty for both curator and visitor guided the “Museum for a Small City” (1942) by German–American architect Ludwig Mies van der Rohe (1886–1969), a design for a one-storey glass box underneath a flat roof and very few permanent interior installations. The potential difficulties such a museum space poses is demonstrated by Mies van der Rohe’s Neue Nationalgalerie (1962–1968) in Berlin where the hall for temporary exhibitions on the upper entrance level suffers from an oversupply of light due to its four all-glass walls. Already at the time of the inaugural exhibition in 1968 floor-to-ceiling curtains were employed to control the flow of light. This reduced the building’s transparency which, however, is important for the experience of the space. Consequently, nowadays, the upper-level exhibition hall is mostly used as a grand foyer for the rather cramped permanent exhibition on the lower floor of the building. Regardless, the “museum without walls” (p. 53)^[29] developed into an important type of exhibition space for the twentieth century.

Yet it was not the ideal museum envisioned as a modernist glass box but the windowless, artificially lit, so-called white box that liberated the arrangement of a display from almost all architectural restraints. Already the Victoria and Albert Museum had experimented in the 1850s with gas lights to extend the opening hours into

the evenings. The collection of the New York Museum of Modern Art was one of the first that was displayed in white boxes, electrically lit, and without direct visual connection to the outside. Not all of these boxes were of purist design. The Yale University Art Gallery (1951–1953), Newhaven, CT, by the architect Louis I(sador). Kahn (1901–74) had a windowless southern façade towards the street that was balanced with a windowed northern façade. Inside, art objects were exhibited under exposed concrete ceilings. Kahn's other two museums, the Kimbell Art Museum (1966–1972), Forth Worth, Texas, and the Yale Center for British Art (1969–1977), Newhaven, broke up progressively the ideal modernist box. The interior of the museum in Texas was covered by narrow vaults, sliced open along the apex in order to let natural light brush down the inner curved surfaces. The second of Kahn's Newhaven projects works with covered atrium spaces that act as light wells and more traditional top lighting.

Flexible, nondetermined exhibition spaces were seen as an opportunity to redefine the relationship between the exhibits, their creator, and the visitor as it was envisioned in exemplary manner by the "open museum" concept of Pontus Hultén (1924–2006), director (1973–1981) of the Musée national d'art moderne, a part of the Centre national d'art et de culture Georges Pompidou in Paris.^[41] The architects Renzo Piano (born 1937) and Richard Rogers (born 1933) realized this idea with a building (1971–1977) that sports its structural systems and technical infrastructure on the outside—color-coded as if it were a machine—while the inside offered, at least initially, open plans on the exhibition floors accessible through purely functional entrances on ground level.

Already earlier museums had avoided overly representative entrances, or abandoned them entirely. The brief flight of stairs up the main entrance at the east end of Munich's Pinakothek was inconspicuously located which was perhaps a pointer to the museum's rational provision of various paths through the exhibition. The few steps at the 1909 building of London's Victoria and Albert Museum invited without much intimidation into a space possibly outside of the most visitors' everyday life. The New York Museum of Modern Art could be entered unceremoniously by slipping directly inside from the pavement. The entrances of the Centre Georges Pompidou were equally functional, but regardless of all attempts to popularize museums, the building was criticized as an element of an urban renewal project that also demolished Les Halles, a nineteenth-century wholesale market. This criticism was part of the postmodern questioning of the dominance of modern architecture to which museum architects responded by citing historic museum buildings, proposing to rescue historic buildings by installing museums, and developing alternative architectural models for the institution.

The turn to historic museum buildings is exemplified by the Neue Staatsgalerie (1977–1984) in Stuttgart,

Germany, designed by the architects James (Frazer) Stirling (1926–1992) and Michael Wilford (born 1938). The building relied on traditional suites of galleries, referenced historical lighting principles like, for example, the ones used in Soane's Dulwich Picture Gallery, and was organized around a circular, open courtyard modeled on the rotunda of Berlin's Altes Museum. A public path cuts through the rotunda and thus balances any possible monumental or even so-called elitist reading of this space. Historic museum architecture was also cited in the Sainsbury Wing (1987–1991) of the National Gallery, London, by Robert Venturi (born 1925), John Rauch (born 1930), and Denise Scott Brown (born 1930) that replaced a modernist design that had attracted public condemnation by Prince Charles. Now a staircase in the tradition of the Museo Pio-Clementino and the Louvre rises to the upper floor with traditional top-lit galleries.

The use of existing buildings for museums added a new civic dimension to the institution as the older structures may have been monuments or had otherwise an important function for a community. Some of the many museums and galleries designed in Italy by the architect Carlo Scarpa (1906–1978) after the end of World War II in Europe preserved from final destruction ruined monuments of the country's history. In Verona, Scarpa carved the Museo Civico di Castelvecchio (1958–1965) out of an old castle by cutting occasionally even through historic walls in order to achieve a symbiotic relationship between the building and the exhibits. Later in the century, the reuse of buildings became more common that had not originally been intended for museums. Between 1980 and 1990, 13 museums were established along the embankment of the river Main in Frankfurt, Germany, to form a Museumsufer. Some occupied new buildings, some refurbished and enlarged historic private homes like, for example, the villa of the Museum für Angewandte Kunst (1982–1984) that was extended with white cubes by the architect Richard (Alan) Meier (born 1934), and the Deutsches Architekturmuseum (1979–1984) that the architect Oswald Matthias Ungers (1926–2007) designed as a house within a house. The scale was mostly domestic so as to match the art works in the case of art museums and to not disturb the urban design pattern of the embankment. From 1980 to 1986 the Paris train station Gare d'Orsay (1898–1900, architect Victor(-Alexandre-Frédéric) Laloux [1850–1937]), was transformed into the Musée d'Orsay by A.C.T. Architecture (Renaud Bardon (born 1942), Pierre Colboc, and Jean-Paul Philippon). The architect Gaetano Aulenti (born 1927) created the interior design for the exhibition of nineteenth-century art and applied art. While in this case the age of the building and exhibits corresponded, former industrial buildings were also attractive because of the contrasting environment they offered, for example, to contemporary installation artists. One of the earliest examples is the Neue Hallen für Kunst in Schaffhausen, Switzerland, a disused textile

factory (1912–1913) that the artist Urs Raussmüller remodeled from 1982 to 1983. Another abandoned industrial building, the monumental Bankside power station (1946–1970, architect Giles Gilbert Scott [1880–1960]) in London was transformed by the architects Jacques Herzog (born 1950) and Pierre De Meuron (born 1950) into the Tate Gallery of Modern Art (1998–2000). While the upper levels offer more conventionally sized gallery spaces, the gigantic former turbine hall challenges artists to conceive site-specific artworks on a scale previously unknown.

Architects also aimed at integrating new museums into cities in ways that made them less monumental. The architect Hans Hollein (born 1934) designed the Städtisches Museum Abteiberg (1972–1982) in Mönchengladbach, Germany, as an urban landscape that avoids most references to traditional museum buildings. Hollein conceived a three-level building that is entered from a platform on top of the highest level. Underneath, two levels of galleries follow a drop in the terrain ending at a museum garden at the lower end of the site. Manifold openings allow for views from the outside into the museum and vice versa, thus connecting directly the building with the urban environment. References to the city's industrial past in the architectural design establish another, more conceptual relationship. While this museum in Germany tried to overcome architecturally expressed civic monumentality, apparently perceived as intimidating, in favor of public accessibility, a later design by Hollein went a step further. In 1990, the architect won a competition for planning a Guggenheim Museum in Salzburg, Austria, whose three floors were to be cut into a mountain within the city limits and lit solely by transparent cones on the latter's top. The design did away with visible architectural links between the museum building and the urban environment and thus seems to question the validity of the historically important conceptual link between the city and the museum as a civic institution. This development, however, did not prevail as the possibly most famous museum of the later twentieth century, the Museo Guggenheim in Bilbao, Spain, is proudly displayed within the city's urban fabric. Like other branches, realized or planned, the Bilbao museum is part of a global expansion of the New York Guggenheim museum. On the local and regional level the museum was essential to a master plan to regenerate economically both the city and the Basque region. The museum's building, an assemblage of titanium sails and waves, was constructed between 1992 to 1997 to plans by the architect Frank O(wen). Gehry (born 1929).

The extraordinary architecture and the economic success of the completed project in Bilbao initiated many new museum buildings at the turn from the twentieth century to the twenty-first. Many institutions commissioned spectacular architectural designs—whose production was helped by ever more sophisticated computer-aided design software—that would function as signature buildings. For

example, the Milwaukee Art Museum, Wisconsin, asked architect and engineer Santiago Calatrava (born 1951) to design an extension that would increase the museum's visibility. The Quadracci Pavilion (1994–2001) is an engineering feat with two moveable wings that shade the vaulted glass roof of the 90 ft tall foyer, one of the mainly non-exhibition spaces that were added to the museum. A signature building with generous foyer space was also the goal of the Akron Art Museum, Ohio, that opened in 2007, after the architecture firm Coop Himmelb(l)au of Wolf D. Prix (born 1942) had won a competition in 2001. A three-storey hall is the heart of the extension that makes little gestures towards the old museum in Akron's former post office (1899). Many recent museum buildings feature such central foyer spaces whose size exceeds what is required for circulation purposes. These spaces cater to the needs of the museum as an economic institution as they help to control numerous visitors to blockbuster exhibitions, offer architecturally exciting environments for donor receptions, and generate possible rental income from private and business functions. Thus the signature building has changed the appearance of museum architecture by emphasizing, sometimes dramatically, a space that, however, has been an element of the museum building at least since Durand drew a circle at the center of his ideal museum plan and Schinkel realized the rotunda in the Berlin Museum.

CONCLUSION

Museums are institutions that are deeply rooted in Western civilization. A specific building type began to emerge the moment when the meaning of the museum changed from primarily being a private study to an exhibition space that was publicly accessible. During the eighteenth century architecturally fundamental question about the spatial organization of the museum were worked out, that the nineteenth century perfected in ideal types of museum buildings. The early twentieth century was dominated by a modernist reaction against these ideal museum types, whereas in the later century and the twenty-first century unique signature buildings inscribed visibly into the urban fabric the changed economic condition of museums.

Museum Collecting and Collections

Robert B. Pickering

Gilcrease Museum and Museum Science and Management Program, University of Tulsa, Tulsa, Oklahoma, U.S.A.

Abstract

Collecting is a central activity to museums. Object-based learning is the underlying principle that museums use to tell their stories to the public through different media such as exhibits, programs, classes, books, and activities. Collecting in museums is usually directed by curators who conduct research, create new knowledge, and present their work through publications, exhibits, and programs. Traditionally, there has always been a tension in museums between saving objects primarily for research versus using objects in educational programs. In recent decades, this tension has become more complicated as a result of other trends relating to changing demographics, new laws, and evolving ethics. In the future, these trends may change how museums build collections.

INTRODUCTION

Museums today come in many sizes, specializations, and perspectives. Most major cities boast of having a number of museums. Art, history, and natural history museums are the most common types. They usually have well-developed audiences and constituents who know what kinds of experiences to expect when they enter the hallowed galleries. In recent decades, many cities, large and small, have developed children's or family museums. To paraphrase Peter Sterling, former director of the Indianapolis Children's Museum, "Children's museums are the only museums defined by audience rather than by subject." Beyond these well-established museums, many different, sometimes quirky, kinds of museums have been opened that focus on the collecting passions of a dedicated and usually wealthy founder or a passionate core group of supporters.

Without doubt, there are more museums and probably more kinds of museums than ever before. Today, over 3,000 of the estimated 17,500 museums in the United States are accredited by the American Association of Museums (AAM), the national organization that sets the standards for professionalism in the field. In addition, there are many other smaller museum organizations that have developed out of regional interests (Colorado Wyoming Association of Museums, CWAM; Mountain-Plains Museum Association, MPMA) or subjects (Museums West Consortium; Association of Science - Technology Centers, ASTC). All of these organizations strive to define practices that assure excellence in collecting practices and collection care, to support a positive working environment for staff, and to provide enjoyable and enriching experiences for visitors.

HISTORY

The idea of museums that provide educational benefits to the public can be traced to the Age of Enlightenment of the seventeenth century. Before that time, royal and noble houses sometimes accumulated objects that reflected the interests and accomplishments of the great names of the time. The collections might have provided personal satisfaction for the owner and have been shared with other royals and nobles, but educating the masses, certainly was not the purpose. Collections and their care were subject to the continuing interest and power of the owners. These collections have sometimes been called "cabinets of curiosities" to denote their rather whimsical and personal origins.^[1] Yet, it was precisely this curiosity about the exotic world being discovered by European explorers that started the museum movement which we know today.

Early American museums were part of this "cabinet of curiosities" tradition. Thomas Jefferson, Benjamin Franklin, and Charles Wilson Peale, among many others started personal collections, many of which became the founding collections of the great museums in Boston, Philadelphia, New York, and other early metropolitan areas.

THREE AGES OF MUSEUMS

In thinking about museum collecting in America since the beginning of the Republic, three "great ages" of museum evolution can be described: the age of collection, the age of exhibition, and the age of education. The first great age of this scheme, the "age of collecting," was part of the larger age of exploration that emanated from Europe. The New World, as it was called by the Europeans who came

here (understanding that it was not new to those people and cultures that were already here), was the source of great wonder, danger, and opportunity for the Europeans who came and saw a very different world from the one to which they were accustomed. The same wonder, danger, and opportunity must have faced the American cultures that were already here. However, that part of the story is beyond the scope of this entry.

Exploration and collecting go together. Many of the ocean going vessels that left Europe to traverse distant oceans and contact different peoples in search of trade and riches brought back examples of the exotic. Yet the quality of the accumulated collections depends on the training of the collector. Many cultural and natural history objects were picked up by the sailors and passengers on the early voyages to America. The first settlers undoubtedly obtained items from the indigenous people they encountered along the eastern coast. However, it is the rare item that has survived the last three centuries intact and with any information about its origins. During the same period, however, there were individuals who sought to systematically collect and document the new and exotic world in which they were living. These early scientists intended that their work and the objects they collected would be preserved for future generations.

Natural history included the rocks, minerals, fossils, plants, and animals of the new country. The indigenous peoples encountered along the way also were seen as part of nature. Many explorers primarily were interested in the potential wealth that might be obtained from finding gold or silver. Only slightly less important, but often forgotten today, were the riches offered by trees and plants that might have medical, ornamental, or commercial uses. Although economic opportunity may have been the main concern, many of the early expeditions included a scientist who recorded the country through which the expedition passed and the people met along the way. As these ventures expanded across the continent, natural historians were there recording new species with their drawings, descriptions, and preserved specimens. Frequently, artists were part of such expeditions to record the new finds. The works of Mark Catesby and John James Audubon are part of the early naturalist/artist tradition just as the images of Karl Bodmer and Le Page du Pratz recorded the people and customs they encountered. Recently, an excellent new version of Prince Maximilian's travel journals, written while exploring the American West in the early 1830s,^[2] has been published. This fine edition also includes excellent illustrations by Karl Bodmer who accompanied the Prince. The Prince and the artist also collected natural history specimens as well as clothing, tools, weapons, and other objects from the American Indian cultures they encountered.

The great age of exploration and collecting continued throughout the eighteenth and nineteenth centuries. In

many institutions, systematic collecting continues today. Many great museums, especially in the seafaring countries of Europe, were founded in the age of exploration to care for and to present the odd and curious relics to local audiences. Oxford University's Ashmolean Museum, founded in 1683, was the first institution in Europe to call itself a museum.^[3] Within this period, wealthy benefactors, sometimes private individuals and corporate capitalists, as well as government agencies sponsored expeditions of discovery and collecting on the North American continent and beyond. As earlier generations of nobles gained a degree of status and fame from their personal collections, so too did the new rich of the Industrial Revolution and the nascent oil industry, gain from their philanthropy toward collecting and the founding of museums to care for their efforts. The names of Carnegie, Rockefeller, Morgan, Field, and others left lasting legacies for this country by founding some of the great museums that still benefit the public today.

This age of collecting and exploration was a heady time for scientists. The entire world was before them. The extraordinary quantity and variety of natural history specimens being collected around the world, required explanation and some means by which all of the rocks, plants, animals, and other humans could be understood. Many of these objects and the people from distant lands were beyond the experience and the understanding of those whose world view was based on the Bible and local tradition. New ideas based on the observations of geologists such as Sir Charles Lyell and naturalists exemplified by Gregor Mendel and Charles Darwin were converging to revolutionize thinking and the way the world was understood. Naturalists and scientists collected, described, curated, and communicated their finds to other scientists who appreciated their descriptions and systematic organization of the natural world. The revolution of evolution had begun. Decision makers in government and commerce also understood the value to these new discoveries; perhaps not in scientific terms but for their potential economic and political impact. Exhibits of this period often were limited to displays of organisms or objects arranged to illustrate the systematic relationships between the specimens.

The second great age of collecting in museums might be thought of as the age of exhibition and dioramas. Perhaps its roots can be traced to the World Fairs of the late nineteenth and early twentieth centuries. The first World Fair was actually the Great Exhibition of Industry of All Nations held in London in 1851.^[3] World Fairs offered an opportunity to bring together the wonders of the industrial world to mass audiences in England and the United States. Major advances in science and technology were presented by the European countries along with the natural history oddities, archaeological exhibits, and exotic races and cultures displayed for the edification and amusement of the public.

In planning America's signature World Fair, the World's Columbian Exposition of 1893 in Chicago, great effort was expended in showcasing past and present cultures from around the world. Frederic Ward Putnam, the director of the anthropology exhibits, and his trusty assistant Franz Boas, sought out, borrowed, and purchased collections of antiquities. George Dorsey, future curator of anthropology at Field Columbian Museum, was sent to South America for collections. Collections representing the Cliff Dwellers of the American Southwest were presented as were W.K. Moorehead's incredible collection of Hopewell artifacts from prehistoric Ohio. Even peoples were on exhibit, not only on the carnival-like Midway, but also next to the anthropology building where Boas encamped a group of Kwakiutl from British Columbia to shock visitors with their savage "cannibal dance." Not to be outdone, the Smithsonian Institution's National Museum mounted its own exhibits featuring the work of Frank Hamilton Cushing among the Zuni Pueblos of New Mexico.

Although the newly appointed University of Chicago anthropologist Frederick Starr supported the educational goal of presenting ancient American cultures through displays, he also had an ulterior motive. He planned and expected that at the end of the Exposition, those massive and valuable collections would come to the Walker Museum of the University of Chicago and thereby be under his control. A good plan from his perspective, but it was not to be. Putnam had lobbied for his vision of a great city museum and influential Chicagoans bought into his plans. Merchant Marshal Field, encouraged by his friend, lumber baron Edward Ayers, gave 1 million dollars to found a museum that became the Field Museum of Natural History. Other Chicago museums, The Museum of Science and Industry (housed in the Fine Arts Building from the World's Fair), the Newberry Library, and the Chicago Academy of Sciences were based on or inspired by the ideals, collections, and architecture of the Columbian Exposition. As varied as these institutions are, as an outgrowth of the Columbian Exposition, their benefit to scientific research, the economic life of Chicago, and the entertainment and education of the public are immeasurable.

Eleven years after the Chicago Fair, St. Louis presented the Louisiana Purchase Exposition. The St. Louis anthropology exhibits topped those in Chicago; it gave new meaning to the concept of "living dioramas."^[4] To justify its imperial adventures, the United States brought in dozens of natives from the Philippines to demonstrate the progress the government had made in educating their colonized dependents. A school for Indians of the United States was installed to exemplify the progress made in raising the savage indigenes up the ladder of progress, and an Indian Olympics was held to complement the International Olympic Games. Pygmies were brought from the Congo Free State, and Frederick Starr was sent to the

Japanese island of Hokaido to bring back a group of Ainu. Although St. Louis did not gain a great museum, the U.S. National Museum was only too eager to incorporate the magnificent displays into its own collections.

In addition to the many scientists who contributed to these memorable fairs, so too did many artists and technicians apply their skills. Alexander Phimister Proctor, a promising young sculptor, was awarded a commission to create some of the massive animal sculptures in the White City of the Exposition. His background as a western outdoorsman brought an authenticity to his work that served him throughout his long career. Artists such as Carl Akeley and Louis Agazziz Fuertes helped design and create fantastic dioramas for Chicago's new museums. Perhaps for the first time in history, dioramas of entire life scenes, sometimes actual, other times contrived, provided a three-dimensional view into the past that made the viewer feel that they were actually seeing the past. The important point is that the idea of re-creating life behind glass—a permanent record of a particular habitat complete with appropriate plants, animals, insects, and all, or a detailed reconstruction of an activity or scene from an ancient culture—was new and exciting both to the public and to the people who were doing the work. Just as we think of the heady excitement of the early days in Silicon Valley and the computer industry, so were the early days of exhibit development also an exciting and invigorating time. Very talented and dedicated individuals envisioned and created museum environments that have educated and entertained generations of viewers.

While the American Museum of Natural History in New York and Chicago's Field Museum were among the earliest to develop this new approach to museums, they were not the last. From coast to coast, the trend to build larger, more detailed dioramas grew. The Hastings Museum of Natural and Cultural History (Nebraska), the Denver Museum of Nature and Science, and the Los Angeles County Museum of Art are examples.

During the years in which the art of the diorama was being developed, collecting did not stop. However, there was a shift in purpose. Much early scientific collection and exhibition was connected to explorations of evolutionary theory. Scientists looked at rocks and under them to find evidence that either supported or refuted Darwin's new approach to understanding the visible world. In fact, scientific collecting continued to develop in sophistication as did other aspects of science. New techniques of preservation, photography, and eventually, film and audio recording, immensely increased and improved the work of scientists in the field. To the scientist, objects are data. As field work produced more and better data, old theories had to be revised and new theories were developed to explain what the scientists were seeing. First and foremost, science is based on observation. As the number of scientists conducting fieldwork increased dramatically, perhaps exponentially, the need to study, store, and explain their

work became more important. The need to systematically organize the increasing collections also became more important. From the earlier focus on specimens in evolutionary research emerged attempts to present the data in its historical context. Thus, the diorama emerged as a way to provide context for specimens.

The age of exhibition, like the age of collecting, has evolved. Advances in computer technology have dramatically improved dioramas but at the same time, signaled their potential demise. In the late 1960s and early 1970s, one of the new terms heard in museums was the “immersion environment.” Perhaps Walt Disney should be given credit here. To say that Disney added new life to static dioramas is an understatement. His revolutionary vision created entire environments which engaged multiple senses and provided a wide range of sensory rich, realistic but safe experiences. That he was able to make it work on such a grand scale represents both genius and great organizational skill. His determination to recreate a version of history or the future that entertained and educated, has come to be known as “edutainment.” The success of Disney’s vision is evidenced by the large paying audiences that have made a trip to the various Disneylands around the world nearly as important as a religious pilgrimage.

While the Disney phenomenon has been viewed by many museum professionals with varying degrees of skepticism, possibly tinged with jealousy,^[5,6] there is no doubt that Disney changed the public’s standards for the kinds of experiences that they expect. Museums have responded by borrowing some of the ideas and techniques from Disney, and merging them with the museum’s mission to present accurate information about nature and culture. In the conflict between entertainment and education, museums usually side with education, but more often today, they

attempt to merge the two. The comfortable compromise is the “immersion concept” which strives to put the visitor in the environment with all of its sights, sounds, and, sometimes, smells. Mechanical and computer technology added movement and change to such displays that could not have been provided in earlier decades.

The rain forest exhibit at the Milwaukee Public Museum, a leader in exhibit design for decades, also led in this new direction. The environment was so rich in detail that it is impossible to absorb the entire experience in one trip. This exhibit had two other characteristics that would soon be developed by others. First, there is a reconstruction of a field station within the exhibit so that the visitor can see not only the “natural” environment of the rain forest, but also the “cultural” environment of human activity. In 2002, the Draper Museum of Natural History opened as the fifth museum of the Buffalo Bill Historical Center in Cody, Wyoming, and the first natural history museum built in the United States in the twenty-first century. One of the philosophical underpinnings of that museum is that today, it is no longer possible to separate natural history from human history. They are so intertwined throughout the world that even the concept of nature untouched by human activity is perhaps a relic of the nineteenth century (Fig. 1).

The second imaginative introduction of the Milwaukee Public Museum’s rain forest exhibit is that one can enter and explore on at least two levels of the massive gallery: the floor level and the forest canopy level. Today, this may seem a small point, but at the time, providing an immersion experience on one level was a novel experience, letting people experience the environment from a totally different vantage point was simple yet brilliant. Providing a second distinct viewing experience had significant implications and major challenges for the design of the space.

Fig. 1 Beginning in the late nineteenth century, museums used dioramas to interpret and convey information. The Milwaukee Public Museum created many lifelike and dynamic exhibits such as this buffalo hunt.

Seeing from many directions required much more detail in this artificially produced environment so that, in fact, it did not look artificial.

Innovations in computer technology also may hasten the end of the diorama as we know it and change the role of objects in museums. So too, the increased ease and availability of travel for larger segments of society, has caused the question to be asked, "Why do we need to build a diorama of a distant place on the planet when people can now go there?" Dioramas are both labor and cost intensive. Every tiny element, a leaf, an insect, or a blade of grass, in a diorama is either completely artificial or has been treated so that it will look natural for decades. The expertise to make dioramas is expensive. Moreover, natural history documentaries made for television or massive IMAX screens can provide much more information, empathy, and impact than can a static diorama. These converging trends are causing museums to rethink the concept of what dioramas and the immersion environment might provide. The computer gaming industry has demonstrated that building a virtual environment is both engaging to the audiences and it need not be limited to either a specific location, such as a museum; it does not even have to be limited to reality!

The age of exhibition may not be at an end but it is evolving into the third age—the age of education that includes access to information and experiential learning. Innovative computer technology already can create virtual objects and environments. Will it replace the museum's need for real objects and physical environments? There is no "right" or obvious answer to that question at this time. In fact, there is no single answer. We are currently living through this change and the results will not be known until the public and museums around the world decide, and put their support behind that which they find most engaging. However, there are some trends worth watching. Many museums are rapidly placing collections online for distant learners. They are developing virtual versions and simulations of real exhibitions. Museums recognize that creating an exhibit, especially traveling or temporary exhibits, is very expensive. Even if the exhibit travels over a period of months or years and goes to four to six cities, eventually, the exhibits are dismantled and disappear. Computers now offer the opportunity to simulate the exhibit in perpetuity and also provide a depth of detailed information, sources, and images that could not be included in a real exhibit. Technically, creating a virtual exhibit is already possible and being done. There is no doubt that virtuals provide a lasting record. The more important question is, "Will the public care?" Will virtual exhibits be sought out and seen by the public in the same way that visitors now return to museums to see real objects or works of art that are important to them? Again, we do not know the answer but many within the museum field are concerned about the answer.

Museums have always been populist institutions, although to varying degrees. The idea that the museum

exists for the public's benefit, education, and enjoyment has been important for a very long time. For much of the twentieth century, and certainly all of the nineteenth, museums did little to influence or mediate the experience other than to provide objects and labels. The Field Museum, so innovative in its work on dioramas and collections research, also was an innovator in public education. Its education department was established in 1922 to offer classes, lectures, field trips, and a wide range of programs for different audiences. Even more impressive, as early as 1912, Field Museum's Harris Loan Program was established to provide artifacts, specimens, and audiovisual material to Chicago area schools. Access to collections became an important part of the museum experience very quickly.

At least since the 1890s, it has been recognized that access to collections provides excellent learning opportunities for teaching and learning. At the same time, using collections for teaching potentially damages the actual specimens and over time will destroy the specimens. Flowers^[7] wrote eloquently about this internal tension. Over 100 years later, this concern still has not been completely resolved, but there are more innovative solutions than in earlier times. Most museums maintain permanent collections for research. Whether the collections are rocks, bird skins, or clothing and textiles, the use of these collections is governed by rules or guidelines. For many museums, the list of people with access is internally restricted to research and collections staff who have the authority and responsibility for those collections. Researchers from outside the institution who have a legitimate reason to work with the collection, have a specific plan of research, and appropriate credentials, usually are granted access. A person from off the street may get access to research collections but not without significant effort.

Over the decades, many education departments have established "education collections" which are available for teaching people of all ages, but primarily for children. Restrictions apply here, too, but access within educational programs does provide children and adults the ability to closely observe and sometimes to touch specimens under the direction of education staff. This kind of access to collections has sometimes been contentious between the curatorial and collections, and education staffs. The reasons for the disagreement are obvious. Curators and collections staffs are responsible for the physical care and long-term preservation of the objects or works. Curators may have actually collected the specimens, and feel proprietary toward them. Understandably, such curators are willing to give access only to those who they trust will treat the objects with the same degree of care and respect.

Educators tend to focus on the audience and the benefit that access provides. That is not to say that educators do not share collections concerns with curators and collections professionals. They do. By working with curators

and collections professionals, education departments have been able to obtain specimens that are representative of the subject and can be used in programs. For example, a paleontologist may have hundreds of examples of a common fossil. After evaluation, the curator may decide that some examples are redundant, i.e., they do not provide any different information from other specimens. These may be transferred to the education department for use in programs. For objects that are more delicate than a fossil, such as an example of Lakota bead work or an ancient pottery vessel, educators have also come up with acceptable practices. The object may be secured in an appropriate container so that the audience can handle the container but not the actual piece itself. A high-quality reproduction of the object may also be produced or purchased so that it can be handled instead of the actual specimen. Educators can usually be counted upon to find ingenious ways to provide effective hands-on experiences for audiences without sacrificing important objects.

As valuable as education collections are, they may have inherent problems. Educators sometimes complain that the objects they are given are essentially, "too good to throw away, but not good enough for the permanent collections." Educators do not want to teach with inappropriate or substandard material. They recognize that to do so diminishes the educational experience and essentially disrespects the audience. One innovative solution to this dilemma has been to eliminate completely the education collection and to create a "use code" for all objects in a permanent collection. One method has been to use the colors of the traffic light to signify appropriate use. For example, a "red code" means that the object is rare, delicate, and important for research. Therefore only curators and collections professionals may handle it and the only appropriate uses are research and exhibition. A "yellow code" means that other museum staffers who have had training in handling collections may handle the object. Yellow code objects are used in teaching situations as long as the educator and collections staffs agree on a safe method for handling. A "green code" means that an object can be handled and may eventually have to be discarded because of wear. For this category, education departments may purchase a number of examples of this kind of item and use them over time, replacing damaged ones as they go. The Children's Museum of Indianapolis began this practice in the late 1980s. For example, as many as Ten copies of a particular musical instrument such as an mbira or a drum might be purchased for use in children's programming. One example would be assigned to the permanent collection and be labeled "red" while the others would carry the "green" code and be used in programs. As one instrument was damaged another "green" one would take its place. In this way, all of the objects would be documented and tracked within the same collections management system, permanent collections built and maintained and yet, use of appropriate objects in programs facilitated.

CURRENT TRENDS AFFECTING COLLECTING

Museums, their collections, and their reasons for collecting are a reflection of society as a whole. Many trends that are part of our changing culture also impact museums. Knell^[8] provides excellent European perspectives on contemporary and future collecting in museums. By their inherent nature, museums tend to be fairly conservative indicators of change, but change comes, nevertheless. It may not be possible to say how museums will collect or what they will collect in the future but there are some trends worth watching.

A globally significant trend is the rise of the digital age and its amazing ability to provide often instantaneous access to collections around the world. Today, even an armchair hobbyist can have access to images and information that only a few decades ago were available only to top specialists in the field. This is a great advance but not without risks.

Just as the exhibits departments struggle with the competition to their exhibits from computers, television documentaries and other forms of entertainment, and education available today, so too do museum educators struggle with how to compete with the ever-widening number of leisure activities and educational opportunities for the public. No one would dispute that more people now have more access to information around the world than at any time in human history. Therefore, the role of the museum as the presenter of information through objects would seem to be diminishing. Yet, a great deal of the information that is available is unmediated; meaning that the veracity or trustworthiness of the information is not assured. Moreover, the experience of seeing or touching authentic objects cannot be replaced, at this time. Perhaps museums will have an expanding role in providing reliable information about the wide range of subjects presented by museums.

A debate currently within the museum world is to what extent does putting images and data from collections on the Web diminish or increase the role of the museum? Certainly, access to data online reduces the need to visit a particular museum. At the same time, many in the museum world believe that once distant audiences see the virtual image, they will want to come and see the real object or a work of art for themselves. In this sense, putting collections on the Web is a grand advertisement for the real thing. This debate rages (if it can be said that any debate rages in the museum world) as this entry is being written. New audience research will determine how the public is deciding if the virtual is an acceptable substitute for the real.

Although the United States of America is a young nation by world standards, many of our museum collections have now been curated for 100 or more years. Many objects, whether an artist's sketch or a garment made from leather, beads, and hair were not made to last forever; their

makers had a shorter term plan in mind. Museums have the responsibility of caring for these collections for our children's children's children—essentially, in perpetuity. If these collections are, in fact, going to survive and be available for research and exhibition for future generations, then conservation of these old collections will become an increasing challenge and cost to museums. The cost of caring for old collections is connected to the cost of making new collections. Many of the great natural history museums have been collecting plant, animal, and geological specimens for a very long time. Today's curators are adding to those collections. Old or newly collected, the collections staff must care for and properly store all of these objects (Fig. 2).

From the perspective of the curator who collects specimens, there are some significant changes that impact collecting today. There are many more laws that restrict the process. The curator, as a representative of the

museum, must be knowledgeable about the appropriate laws and make sure that the museum complies with all applicable laws. A museum that does not follow the law loses credibility, and very likely, its audience and its financial support. Individuals and museums that do not follow the laws are liable to legal action.

As the principal collectors in the museum, curators often determine what will be collected. Research interests have changed over time. In earlier generations, a natural history curator might have focused on the systematic study of a group of plants or animals. Today, a natural history researcher might be delving into DNA rather than looking at bones or feathers. Although those old collections of bones or feathers may yield the DNA needed by contemporary researchers,^[9] they can be used to answer new questions. A hundred years ago, an anthropologist might have been out in the field acquiring objects from people in a culture that the anthropologist was sure would be extinct very soon. Perhaps he would have collected some oral histories and stories, too, but museums wanted objects. Today, the anthropologist is more likely to be working with tribal peoples to better understand the objects that were collected. As a result of Native American Graves Protection and Repatriation Act (NAGPRA), the anthropologist may work with federally recognized U.S. tribes to return important sacred and ceremonial objects to the tribe. An art curator today may continue to focus on past periods of artists and art styles and yet, the late nineteenth and the twentieth centuries spawned an explosion of new artists whose contributions and places in history are yet to be determined.

That curators have a central role in collection development is unmistakable, yet the training of curators is another trend that will affect museums in the future. A concern commonly voiced within anthropology and history museums is that for more than a generation, graduate schools have tended to diminish the importance of material culture studies, i.e., working with and researching real objects, (archaeologists sometimes call this “reading” objects) and have emphasized theory and the intellectual aspect of research. While this trend makes considerable sense for creating the next generation of college professors, it means that the skills for handling, studying, and understanding objects are not being transferred to the next generation of curators. Museums and their curators also are interested in the latest theories and the innovations of research, but we also have the collections in our care. If new curators do not have advanced skills in collections-based research and the ability to discriminate between genuine versus modified or fake objects, then the museum and, in fact, the entire public suffers.

While curators direct the building of collections from the inside of the museum, collectors and donors sometimes direct collecting from the outside. Many great collections have been assembled in virtually every collecting field by dedicated and wealthy individuals. Private

Fig. 2 Older objects, especially those made from perishable materials, will need consistent care to preserve these treasures for future generations. Cheyenne (Tsistsistas) cradle, ca. 1880; wood, tanned hide, glass beads, brass tacks, tin cones, porcupine quills, horsehair.

collecting and collecting for museums can be quite different.^[10] However, the history of museums exemplifies how the two merge. Often as they approach the end of their lives or perhaps just the end of their interest in one collecting area, they look for a museum to care for their collections. Many times, this opportunity is a great benefit to the museum. Collectors frequently have more money to spend on acquisitions than do most museums. When the museum and collector work together, the relationship can be very beneficial to all parties including the public who will have access to the once private collection.

The ethics of collecting is evolving rapidly and impacts virtually all areas of collecting and research. The international movement to redress grievances related to art and other possessions stolen by the Nazis is a very visible example but there are others. From stolen religious icons to objects looted from national museums during the Iraq war, museums often find that they are being offered cultural treasures through dealers and donors. Today, the ability to establish clear title and to demonstrate that objects were legally sold and legally obtained by the museum is expected. A museum that does not diligently research such high profile works may find itself in legal difficulty and risk a public relations disaster.

The American NAGRPA law, various United Nations treaties, and laws from individual countries that strive to put control of cultural objects back into the hands from which they were taken are having an increasing impact on museum ethics. These laws pertain to objects, yet their importance is that they redefine the relationship of cultures; usually an indigenous one and a dominant, if not an imperial one. Returning objects does not negate past wrongs but it may well provide a reorientation of respect and responsibility between cultures. Numerous volumes have come out in recent years that explore various aspects of collecting cultural artifacts and relations between museums and indigenous peoples.^[11–14]

As positive as these new ethical positions are, they have their extremist proponents too. For example, archaeology explores past cultures and helps this and future generations understand more about how human beings evolved and cultures developed across the world. Archaeology strives to be the scientific and objective way of looking into past cultures. Outside of science, every culture has its own traditions and stories about their origins, their own past, and perhaps their relationships with their neighbors. As previously dominated cultures assert themselves, they also promote their own versions of their histories and sometimes diminish or dismiss the scientific view provided by archaeology. This perspective is understandable, but if taken to an extreme, it refutes archaeology as a legitimate discipline.

While curators direct collecting in many ways, there are cultural trends outside the museum that pertain.^{[15], [16]} For most of the history of this country, the museum-going majority was Euro-American in ethnicity. Laws and

practices often eliminated opportunities for racial minorities to take advantage of museums. Cost of admission impacted all poor people regardless of ethnicity. Those restrictions do not apply so much today but there is another aspect of ethnicity that does. The impact of increasing ethnic and cultural diversity is seen in schools, in the workplace, and in churches. Changing demographics also impacts museums. Does every ethnic group have the same museum experience that has evolved in Euro-American museums for more than a century? Do all cultures value the museum experience in the same way, to the same extent? Forward thinking museums will engage their audiences in providing answers to those and other related questions. Together, museums and their audiences will find the answers that work for them. One impact of greater audience diversity is clear; visitors want to see their own histories. For museums of art, history, and anthropology, satisfying an increasingly multicultural audience will require more efforts toward representing cultures that reflect our current society. Alternatively, communities that have felt marginalized or excluded may choose to create their own museums. The Smithsonian's new National Museum of the American Indian and the proposed National Museum of African American History and Culture are prominent examples.

In addition to ethnic differences in perspectives on museums, generational differences also contribute to the changing museum environment. Tom Brokaw's book, *The Greatest Generation*,^[17] presented extraordinary acts performed by ordinary people during World War II, both at war and at home. Those who were fortunate to return at all, came home, changed out of their uniforms, and built their lives and this country. A couple of characteristics are worthy of note in the museum context. That generation understood personal sacrifice. Many were committed to making their own lives and the world a better place. They joined organizations, volunteered their time, and gave and raised money for all kinds of public causes. Some members of that generation also were significant collectors of paintings, historical documents, firearms, and many kinds of objects that interest museums.

As that generation passes, many of those collections are being offered to museums. Portions or entire estates are being given to museums as a perpetual memorial to the collector or benefactor. Many museums are also directly benefited from the volunteers who came to museums to learn and to give back to society. As this incredible generation passes, museums, and perhaps our entire society, become poorer for it. There is a critical question as to the philanthropic interests and patterns of giving by subsequent generations. Will the baby boomers and their children be as generous with their time and money? The answer is critical to museums and society in the future.

Beyond demographics, there are psychographics—the interests, needs, and wants that determine the choices people make. Demographics may be thought of as descriptive

of an audience while psychographics may be predictive of interests and behaviors. Today's researchers in museums are interested in both. Will the generation now entering kindergarten have the same interests as their grandparents? Will they want to go to a specific place to learn about dinosaurs, ancient cultures, and the art of previous generations? The answers are not readily apparent, but to be successful, museums will have to continually struggle to be relevant and engaging to each new generation.

CONCLUSION

Collecting and preserving objects or works of art and providing access to these collections are the core activities of museums. Over the last three centuries, museums have seen the purposes and techniques of collecting and storing objects change dramatically. Yet, the purpose of collecting—creating new knowledge through research and presenting that knowledge to the public—is still pivotal to the future of museums. New technologies have not only impacted how things are collected, technology now allows the collecting of data that was virtually invisible to former generations. The digital revolution is recasting the opportunities to access the storehouse of knowledge that museum collections represent.

Museums are sometimes thought of as rather quiet, unchanging places where few things happen fast, if at all. There may have been a time when that was true; it is not any longer. To continue to be valued by the public, museums will continue to evolve through internal efforts and external pressures and needs. Museums will continue to reflect what is important to the culture of which they are part. As those cultures evolve, so too will the museum.

Collections Information and Access, San Francisco Museum of Modern Art, San Francisco, California, U.S.A.

Richard Urban

Graduate School of Library and Information Science, University of Illinois, Champaign, Illinois, U.S.A.

Abstract

The museum information professional's association, the Museum Computer Network (MCN), was organized in 1967 during the early years of computerization in museums. Throughout its history MCN has provided conferences, news, and networking opportunities to its members. Through a discussion of key points in the group's development and current activity, the 40 year history of the association is briefly explored.

INTRODUCTION

The Museum Computer Network (MCN), formed in 1967, is a professional association that supports the greater museum community by providing continuing opportunities to explore, implement, and disseminate new technologies and best practices in the field. MCN draws its members from the ranks of museum staff who manage museum Web sites, network infrastructures, visitor services systems, and museum collection management and registration systems.

MCN provides professional development and educational opportunities through its annual conference. A Web site and the MCN-L listserv provide members opportunities to communicate throughout the rest of the year.

This entry offers a brief history of the organization from its inception in the late 1960s through the present.

ORIGINS

In 1965, the New York University (NYU) established the Institute for Computer Research in the Humanities (ICRH) under the leadership of computer scientist Dr. Jack Heller. During its first years of operation, the ICRH developed automation tools for NYU's library and completed the first electronic indexes of the *Répertoire International de Littérature Musicale (RILM)* and the *Revista Filología Española*. Working with the Dag Hammarskjöld Library, Heller created a suite of programs he called the *General Retrieval and Information Processor for Humanities Oriented Studies (GRIPHOS)*.

Heller and the ICRH came to the attention of staff at the Metropolitan Museum of Art in late 1966. Within the next few months, ICRH developed processes for Carl C.

Dauterman to analyze porcelain in the Met's collection and had begun exploring a project to create an electronic index of the Met's *Bulletin*. During a visit to the museum, Heller met registrar William D. Wilkerson, who introduced him to the challenges of recording information about the Metropolitan's collections and instigated the series of meetings that was to follow.

In the spring of 1967, directors from 15 New York area museums met to explore ways Heller's work could be used beyond the Met. With funding from the New York Council of the Arts and the Old Dominion Foundation, the consortium formed the MCN to create a prototype system for a shared museum data bank. The administrative committee for the project, chaired by Wilkerson, selected Everett Ellin as its first executive director.

The project recruited curators and registrars to develop a data dictionary that would accommodate the diverse methods used to describe museum collections. The resulting tagged record format allowed for the description of individual objects with separate records for artist biographical information and reference citations. Heller's GRIPHOS system provided the information storage, search, and retrieval infrastructures for the records.

MCN and the Metropolitan Museum of Art, with funding from IBM, organized the first U.S. conference on the topic of museum computing in April 1968. This would be the first of many promotional efforts by Ellin, who was concerned about the growing information crisis in America's museums. In an appendix to the American Association of Museum's (AAM's) influential *Belmont Report*, he described MCN's vision for shared national and international museum data banks that would not only improve museum management practices but also would provide unprecedented access for researchers. Because of the expected costs, MCN

advocated for a single network that would handle data for all the museums across the country.

INCORPORATION AND GROWTH

In June 1969, Jack Heller resigned his position at NYU and accepted a position at the State University of New York (SUNY) at Stony Brook. The original grant funding for the MCN pilot project ended in 1970. Of the original 15 partners, only the Metropolitan Museum and the Museum of Modern Art continued to catalog their collections using computerized methods and their own operating funds.

In 1972, the MCN was formally incorporated in the state of New York with David Vance as its first president. An “administrative committee” was comprised of representatives from institutions who had been involved in MCN’s formation. Museums could join to receive consultation and advice about computerization projects or as full members with access to MCN software and hardware resources.

In addition to a change in funding structure, this transition marked a change of what kind of “network” MCN represented. Originally conceived as a physical computer network, MCN was to become part of a growing professional network of related cultural heritage computerization projects. Museum Computer Network would be one of the cofounders of a related group known as the Museum Data-Bank Coordinating Committee, which sought to find connections and opportunities for sharing work among a variety of museums including archeology, ethnography, history, natural science, and art museums.

Museum Computer Network was able to attract a number of large institutions as members, allowing it to continue operations and development of the GRIPHOS system. Especially important was the decision by Robert G. Chenhall to select the MCN/GRIPHOS system for the Arkansas Archaeological Survey, which encouraged other statewide surveys to take a similar path.

During this period, MCN began to regularly host annual conferences. Initially the conferences focused on issues relevant for GRIPHOS users, however, over time the conferences attracted representatives from other museums who had not yet implemented a computerized system.

In 1974, David Vance and the MCN office joined Jack Heller at SUNY-Stony Brook.

FROM INSTITUTIONS TO INDIVIDUALS

Toward the end of the 1970s, the operating systems found on IBMs mainframe computers were quickly becoming obsolete, foreshadowing the end for GRIPHOS, which had been tightly tied to those operating systems.

This tight integration had already limited the adoption of GRIPHOS in environments that used non-IBM

hardware, a problem for museums which often relied on local university computing centers. Updated packages and user manuals continued to be released, but fewer MCN members were able to support the GRIPHOS software. Vance and Heller worked on migrating GRIPHOS to emerging minicomputers in 1981, but these efforts were soon overshadowed by the microcomputer revolution.

The computer revolution which was changing the business world in the 1980s was reflected in the rapid changes occurring at MCN as well. Cheaper desktop computers along with more accessible software made incorporating computers into their operations more realistic for some museums. This caused the increase in MCN’s activity which was evidenced in the composition of *Spectra*. A different audience was looking to MCN for advice on computerization, and for an affinity group of like-minded museum professionals.

While some longtime MCN members continued to advocate for the centralized approach that the organization had been founded upon, museum computerization efforts were increasingly localized with little demand for the large mainframe systems of the 1970s. With dwindling support, the GRIPHOS system was officially retired in 1979.

During MCN’s “mainframe” period, only institutions could be members of the organization. Reflecting the change to personal computing, the organization opened up membership to individuals for the first time in 1981. The organization soon attracted a broad spectrum of the museum community using a variety of different approaches to automating their collections.

The MCN Board decided the time had come to make major changes in MCN’s structure, some of which were precipitated by funding cutbacks at SUNY-Stony Brook. The State University of New Yorks withdrawal of support meant MCN could no longer afford to pay its longtime staff member and president, David Vance. Vance stepped down as president in early 1986 and was replaced by Ron Kley. The board created a new model of a short-term volunteer president working alongside a grant-funded executive director.

Throughout the 1980s, MCN moved further away from the original vision of a centralized system, choosing instead to emphasize the development of data standards that would allow the exchange of museum information between systems that met local needs. These efforts retained the spirit of the original network, without forcing museums to adopt a single application or hardware platform.

CONSORTIUM FOR THE COMPUTER INTERCHANGE OF MUSEUM INFORMATION

Museum Computer Network continued to envision a structured flow of information between museums and at the end of the 1980s received grants from the National

Endowment for the Humanities and the Pew Trust to create the Computer Interchange of Museum Information (the CIMI project).^[1] Headed by David Bearman, the project brought together a group of museum professionals and network industry staff.

Computer Interchange of Museum Information became an independent entity and produced the CIMI Standards Framework in 1993. The Framework recommended the standard fields which could later be used for interchange of information between museums and served as the basis for several test projects. Throughout the 1990s, the CIMI group continued their endeavors; among the members were the Getty Information Institute, the Canadian Heritage Information Network (CHIN), the Eastman Kodak, the Smithsonian, the Museum Documentation Association in the U.K., and of course, MCN.

CONFERENCES AND COLLABORATIONS

Since the first conference in 1968 MCN continued to produce its annual conferences, sharing information on the challenges, and successes of introducing technology into the museum environment. In 1979, MCN held the first conference to which people outside of the group of MCN institutional members were invited. This approach brought in new attitudes and new life into the organization.

Conferences were held in cities all over North America, usually at museums or facilities where members worked. The 1980 conference hosted the first public presentation of the Report of the North American Planning Conference, held at SUNY-Stony Brook that year.

The 1985 meeting was hosted by Dr. Jaime Litvak King of the University of Mexico, and included demonstrations on microcomputers, software, and Apple Mac hardware. The meeting featured preconference workshops for the first time.

Delegates at MCN's annual meeting in Pittsburgh in 1992 welcomed a surprise visitor—presidential hopeful Bill Clinton. Clinton spoke with MCN members who were so impressed that the fall 1992 *Spectra* included a list of delegates who had shaken his hand. Bill Weinstein was the record holder at four handshakes.

San Diego was the setting in 1995 when MCN and the International Conference on Hypermedia and Interactivity in Museums (ICHIM) held a joint conference which kicked off many of the archiving and online efforts of the next several years. Museum Computer Network's president at the time, Leslie Johnston, initiated a relationship with the Smithsonian Institution's archives to store MCN's records, where they are still kept.^[2] Museum Computer Network's Web site went online shortly thereafter.

Museum Computer Network continued to forge informal alliances with professional organizations and to produce conferences in conjunction with these groups.

Among the collaborators and conference hosts were the CHIN, the Association of Moving Image Archivists (AMIA), the Northeast Documentation Conservation Center (NEDCC), the National Initiative for a Networked Cultural Heritage (NINCH), and numerous others. Museum Computer Network is also an official affiliate organization of the AAMs.

U.S. CONGRESS

The Internet and World Wide Web were expanding rapidly during the early 1990s, and the U.S. Congress was moving to begin regulating and codifying the use of what it termed the "Information Superhighway." The High Performance Computing and Communication Act of 1991 (the Gore bill) led to the introduction of legislation proposed in Congress to support government information and cultural efforts on the Internet.

Early versions of the legislation did not mention museums specifically. Including museums in information superhighway legislation became a priority for Diane Zorich, President of MCN in 1994. Zorich's efforts and the efforts of many others on behalf of the museum community were successful in August of 1994 as stated in a *Spectra* article from the Summer 1994 issue. *Spectra* reproduced AAMs entire announcement, written by Michael Roark from their Government and Public Affairs office. "The Senate Commerce Committee today voted to guarantee the nation's 8000 museums a place in the National Information Infrastructure under the Communications Act of 1994. Museum images, texts, programming, and personnel will soon be accessible to highway travelers." The gist of the bill, according to Roark, was to deregulate sectors of telecommunications industries in exchange for industry support for schools, libraries, hospitals, and museums.

PUBLICATIONS

Information about MCN's activities was first published in the *ICRH Newsletter* along with updates about the progress of the GRIPHOS project which appeared in *Computers in the Humanities* and *Museum News*.

After David Vance relocated to Stony Brook in 1974, he wrote the "MCNews" column that appeared in *Spectra*, the newsletter for the Center for Contemporary Arts and Letters. By 1983, *Spectra* was entirely dedicated to news about MCN activities. The publication schedule was sometimes sporadic but generally followed the quarter system. In 1986, 2600 issues were mailed to 41 countries while *Spectra* was still being distributed at no charge. Issues with literature reviews, featured articles, and conference reports were often done on an extremely low budget, but always with professional editors publishing the

sought-after journal. By 1987, organizational focus shifted towards expanding services and working with the AAMs on cooperative ventures. Consequently, the Board decided to expand *Spectra* contents and begin charging for subscriptions. In 1996, the newsletter underwent a complete redesign and by 1999 with the departure of longtime editor Suzanne Quigley, it moved away from MCN news completely. Guest editors organized *Spectra* between 1999 and 2002, when it was self-described as “not a scholarly journal, but rather a community-based current awareness publication focusing on issues and projects of interest to museum information professionals.” The new millennium was celebrated with a special small format issue guest edited by Steve Dietz and Scott Sayre featuring thoughts and prophecies from 75 colleagues.

By 2002 rising production costs far out-distanced MCN’s subscribers’ and sponsors’ capacity to pay for them; and the Board reluctantly suspended *Spectra*. The Board’s hope was that the journal would eventually be revived on the MCN Web site, but competition for limited resources has not permitted its return.

Spectra’s suspension occurred at a dark time for volunteer organizations and membership associations in particular. The “dot com” boom was over, and the tragedies of September 11, 2001 had just occurred. The U.S. economy was experiencing a downturn wherein nonprofit organizations, including museums everywhere, suffered. Non-profits’ budget cuts translated into fewer members for MCN and fewer travel dollars for members.

INTERACTIVE AND ONLINE

The computer ubiquity envisioned for businesses in the 1970s gradually became reality in the 1990s, with the wider availability of personal computers, access to e-mail, and the Internet. Various programs were founded around the country, such as the Electronic Frontier Foundation; the Museum Informatics Project at the University of California, Berkeley; and NINCH. The Getty Art History Information Project launched their Web site and the Networked Access initiative. Museum Computer Network members quickly embraced new technologies which were becoming more and more affordable for smaller institutions not supported by universities or other large entities. The 1990s were a time of growth and expansion for MCN.

The International Conference on Hypermedia and Interactivity in Museums began to hold conferences which focused on the presentation and Web tools in the international museum community. Also in 1996, MCN created their first Internet home page and a discussion list; many museums’ Web pages were launched, and thousands of Web pages from all over the world began to come online. In the late 1990s, MCN continued developing its own Web site,^[3] which was completely overhauled in 2005.

ANSWERS CHANGE, QUESTIONS REMAIN THE SAME

Over the last 40 years, cycles and recurring themes have occupied the MCN Board. Most of the plans centered around continuing to produce the high-quality conferences and publications for which MCN was well known; and to foster greater member involvement in planning and programs. Board of Directors’ strategic planning retreats dealt with these key issues every few years. Each time the focus of the organization shifted slightly, but the premises of supporting the use of technology in museums and supporting museum information professionals did not.

As evidenced in *Spectra* over its 28 year history, desperate straits were always balanced by periods of optimism and growth. Expenses for MCN’s ventures increased dramatically over the years and funding was nearly always an issue. Several different management models were tried during MCN’s lifetime, including a full-time Executive Director, a part-time Program Director, and various management companies performing administrative duties. Currently, MCN’s administrative functions are managed by McPherson Clarke, a Canadian association management company.

MCN TODAY

Governance

Since its incorporation in 1972, MCN has had a volunteer Board of Directors, usually composed of 12 people. Each director is elected for a term of 3 years, and may serve two terms in succession. Directors are expected to contribute to MCN’s programs throughout their terms and to participate in several committees, such as Communications, Leadership Development, Membership, Finance, and Marketing. Directors meet monthly by phone and twice a year in person. The Executive Committee handles many of the organization’s immediate concerns and is composed of the board officers. The President, Vice President/President-Elect, Treasurer, and Secretary form the Executive Committee. The Treasurer and Secretary are appointed from the Board of Directors, serving a renewable 1 year term. The Vice President serves in that capacity for 1 year and as President for 1 year. The Past President also serves 1 year in an advisory capacity.

Over the years, the bylaws have continued to develop and change. Museum Computer Network bylaws are available in the About Us section of the Web site.^[4] The latest strategic plan is also available in the About Us section of the Web site.^[5]

SIGs and Chapters

In 1997, MCN created the mechanism to form Special Interest Groups (SIGs) with the establishment of the SIG

Charter.^[6] Each SIG provides a forum for MCN members to pursue specific subjects while MCN as a whole focuses on its members' more general concerns. Special Interest Groups may also represent geographic regions, such as the active California SIG.

Contributing to fields within the museum information profession, SIGs provide opportunities for learning new skills, leadership, and growth. Where communication with the MCN Board is indicated, this usually occurs through the Board's SIG Liaison; in some cases, it includes communication with other officers as noted.

Over the years, MCN has formed relationships with various international groups but never formalized these relationships. In 2006, MCN created the mechanism to form separate regional chapters outside North America. In March 2007,

...A ceremony marking the establishment of MCN in Taiwan was held at the National Science Council, attended by MCN President Marla Misunas, Academia Sinica Vice President Liu Tsui-jung, and Academia Sinica academician Ovid J. L. Tzeng. Liu also chairs the state-operated National Digital Archives Program (NDAP) which cooperates with the MCN in the organization of the MCN's branch office in Taiwan.^[7]

Dr. Der-Tsai Lee, Director of the Institute of Information Science, Distinguished Research Fellow, and Director of Research and Development for the Digital Archive Technologies Program in Taipei, Taiwan, is the chapter's first President.

CONFERENCES LOOK TO THE FUTURE—AND THE PAST

Despite the economic downturn of the 2000s, MCN continued to produce strong conferences. Innovative presentations on current topics drew MCN members both experienced and new to its conferences. The conference theme of 2004, "Great Technology for Collections, Confluence, and Community," focused on the intersection of museums, libraries, and archives, which drew delegates from all three disciplines. This intersection too is a recurring theme, as seen when looking back at *Spectra*, Winter 1989, when a member wrote in for help integrating cataloging information for the three different areas within a museum. The topic of integration remains fluid, as museums couple and decouple their electronic resources.

"Digits Fugit," MCN's 2005 conference, focused on digital preservation and partnered with the Northeast Documentation Association, providing an entire week's worth of educational programs in Boston.

The 34th annual conference in 2006, "Access to Assets: Return on Investment," took an entirely practical approach. The conference showed delegates how the sometimes

intangible educational programming for which they are responsible can be shown to be integral to their museum's operation. And whether they bring in funds directly or not, the public expects to have these programs, or will go to other institutions that do.

In 2007, the annual conference celebrated MCN's 40th anniversary, "Building Content, Building Community: 40 Years of Museum Information and Technology." Conference pricing was reduced and conference programming expanded. A full day of plenary sessions focusing on leadership preceded the usual educational sessions and demonstrations, which took place over the remaining 3 days.

COMMUNICATIONS

While publication of *Spectra* ended in 2002, MCN continues to place an emphasis on providing a place for museum technology professionals to communicate. Since 1996, MCN has maintained the MCN-L listserv, which serves as the primary forum for museum professionals to discuss topics from day-to-day operation of a museum's technology infrastructure to the impact of emerging technologies on current practice.

FUTURE DIRECTIONS

Museum Computer Network's strategic plan for the years 2007–2010 is comprised of five major sections: Communication, Finance, Leadership Development, Membership, and Programs and Education. Each section of the plan integrates with the other four to establish and maintain initiatives and goals outlined in the plan. Among the goals are those with which MCN boards of directors have long been concerned: increasing membership, improving the association's financial health, continuing to produce quality programs, and keeping members actively involved in program planning. The methods by which the board and committees of the organization work are changing—for example, the board now actively uses its own wiki—but the core aims of the organization remain helping museum staff use technology effectively and helping museum information professionals advance their careers.

Museum Informatics

Paul F. Marty

College of Communication and Information, Florida State University, Tallahassee, Florida, U.S.A.

Abstract

Museum informatics is the study of the sociotechnical interactions that take place at the intersection of people, information, and technology in museums. This entry presents an overview of museum informatics, covering such topics as information representation, information organization and access, information management, information technology, information interactions, and information professionals in museums. It explores the impact of information science and technology on museums, museum professionals, and museum visitors, and argues that museum researchers must take a sociotechnical approach to studying the use of information resources and technologies in museums.

INTRODUCTION

Museum informatics is the study of the sociotechnical interactions that take place at the intersection of people, information, and technology in museums.^[1,2] Over the past few decades, museum researchers and professionals have explored the impact of information science and technology on the people who use museum resources. Museum professionals and museum visitors—including curators, registrars, school children, and scholars—have found their understanding of what museums can and should do dramatically changed by the introduction of new information resources and technologies into museums.^[3]

Museums have traditionally served as repositories of objects for the purposes of research, preservation, and education.^[4] For thousands of years, museums have acquired, stored, and exhibited objects of art, cultural heritage, natural history, science, and technology. Yet museums are not only repositories of objects; they are repositories of knowledge.^[5,6] The modern museum is an information service organization where information about museum collections is just as important as the collections themselves.^[7,8] As knowledge repositories, museums store knowledge; as information service organizations, they make this knowledge accessible and usable for their visitors.

Today's visitors to museums—from elementary school children to academic researchers—expect instant access to extensive information about every object in the museum's collections. To meet these expectations, and to serve their clients as effectively as possible, museum professionals have become more skilled in managing information resources in museums.^[9] They have honed their expertise in information organization and access, become more sophisticated in the application of information technologies designed or adapted for use in museums, and developed skills in such areas as digitization, information

storage and retrieval, collections management systems, and Web-based educational outreach.^[10]

The changing needs and expectations of the users of museum information resources have prompted corresponding changes in the capabilities and services provided by museums. This entry will examine those changes, and explore the impact of new information technologies on museums, museum professionals, and museum visitors.

Taking its cue from the scholarly and practitioner literature published on this topic over the past few decades, this entry will examine museum informatics within the context of the museum profession. It is only recently that the field of museum informatics has begun to develop the critical framing and discourse necessary for the advancement of the field as a theoretical area in its own right. While this entry, therefore, focuses primarily on the professional activities of museum informatics, it concludes with a discussion of the importance of moving from practice to theory, and the future of museum informatics as a research area.

INFORMATION RESOURCES IN MUSEUMS

Many types of information resources are important to museums. The most important information resource that any museum possesses is its collection of artifacts. These objects are valuable documents in their own right, providing information about the world's culture, art, history, science, and nature.

Equally important, however, is the extensive information that museum professionals possess about the objects in their care. When a museum acquires a new collection, information about each object is recorded and organized. Museum professionals must know what they have, when they collected it, why it is of significance, where it came from, what condition it is in, etc. They record specific data

about each object such as nomenclature classifications; physical dimensions; material analyses; geographical, cultural, and temporal designations; artifact histories; scholarly remarks; condition and conservation records; research notes; and so on. They also maintain related information resources such as donor files, accession records, exhibit histories, research studies, temporary loans records, visitor attendance reports, information requests, etc. (Buck and Gilmore^[11] for more information about museum records).

Information Representation

When working with information about their collections, museum professionals rely on principles of information representation to create information surrogates or aggregates that can be manipulated more easily than physical artifacts. Surrogates are created by taking information entities and making them physically or informationally smaller (e.g., catalog card records), while aggregates are single resources that represent groups of information entities based on shared data (e.g., a list of all artifacts accessioned in the same year). Information surrogates and aggregates are usually easier and faster to handle than artifacts themselves, especially when searching, sorting, or manipulating museum resources. In addition, working with object surrogates is safer for artifacts, as museum professionals can research collections, develop exhibits, and work with scholars while artifacts remain safely in storage.

Over the years, museum professionals have used a wide range of tools (such as ledgers, card catalogs, computer databases, and digital collections management systems) to organize and provide access to information representations in museums. While no information representation can duplicate the physical artifact in its entirety, access to a sufficiently detailed information representation can meet the needs of many users, including researchers, scholars, teachers, students, and the general public. For information resources to effectively meet the needs of the museum's users, information must be properly organized and easily accessible.

INFORMATION ORGANIZATION AND ACCESS IN MUSEUMS

Until the 1960s, information resources about museum artifacts were organized into paper records and card files.^[12] There were many drawbacks to this paper-based system, especially in terms of information access: only a limited number of individuals could access the files at any one time; and access was restricted to only a few data points, usually accession number, donor name, and occasionally the object's name or classification.

With such a system, answering questions such as "When did we receive this particular artifact?" or "What has this donor given us?" might be simple enough tasks

(assuming the card files were kept up-to-date). Searching through and sorting records to answer more sophisticated questions could be laborious and time-consuming. Within the limitations of paper-based systems, certain questions prove virtually impossible to answer, including: "How many oil-based paintings do we have that were painted before 1450?" or "Do we have sufficient numbers and types of shoes to create an exhibit illustrating the history of shoemaking over the past 500 years?" When faced with such questions, even the most knowledgeable and skilled museum employees might be unable to provide satisfactory answers.

This situation improved with the introduction of modern, computerized systems for museum cataloging.^[13] Museum professionals were now able to search and sort digital records about their collections using almost any database field. They could store more information about their artifacts, and they could share data more easily with other institutions. Museums had the potential to work together to improve the quality of their information resources and provide better, more useful, and more accurate information to their users; but the realization of this potential did not turn out to be an easy task.

There were few accepted standards for organizing information within museums, and organizational methods were typically institution specific and varied greatly from museum to museum. Given the inherent uniqueness of museum artifacts, it was impossible for one museum to document an object and then share that information with other institutions with the same object. No two institutions would record the same information in their ledgers, or use the same terminology when describing their collections. How, then, could museums develop standards to improve the quality of their records and more easily share data about their collections?

Standards and Metadata

There have been many attempts to create data content, structure, and value standards for documenting and describing museum artifacts.^[14] Cultural heritage institutions, for instance, frequently classify collections of man-made objects using a nomenclature system developed in 1978 by Robert G. Chenhall,^[15] later revised and expanded by James Blackaby et al.^[16] It is difficult to develop a classification system that works equally well across all institutions with widely different kinds of collections. Museum professionals attempting to use Chenhall's nomenclature may encounter many difficult questions, such as: Should an ancient Egyptian document written on a torn piece of papyrus be classified as a material fragment or according to the content of the document? or Should a wine jug from ancient Greece be classified under the generic term "Pitcher, Wine" or the specific term "Red Figure Oinochoe?" Different institutions tend to answer such questions in their own way, thereby

making it very difficult to establish standards that can be upheld by all organizations.

Museum professionals at many different institutions are working to solve these problems. The Getty Research Institute has developed detailed vocabularies and thesauri specifically for the use of museums.^[17] The products of their research include structured vocabularies such as the Art and Architecture Thesaurus (which provides 131,000 terms for describing cultural materials), the Union List of Artist Names (which contains 293,000 names of artists and architects), and the Thesaurus of Geographic Names (which includes 1.1 million terms for geographical and historical locations). The Getty Research Institute has also developed the Categories for the Description of Works of Art, which establishes a data content standard for describing museum objects and images.

International organizations have developed and evaluated metadata standards to see whether they can be used when describing museum artifacts. The International Committee for Documentation (CIDOC) of the International Council of Museums (ICOM) has led the development of the Conceptual Reference Model (CRM), providing perhaps the most complete model for describing concepts and relationships when documenting cultural heritage objects (<http://cidoc.ics.forth.gr/>). During the late 1990s, the Consortium for the Computer Interchange of Museum Information (CIMI) evaluated the effectiveness of the Dublin Core Standard for describing museum artifacts, concluding that Dublin Core elements are useful to cultural heritage institutions in the abstract, but potentially problematic when used for institution-specific needs. More recently, academic researchers have been investigating the use of Extensible Markup Language (XML) for describing museum artifacts, and exploring the potential of the Open Archives Initiative for harvesting museum metadata for collections repositories.^[18]

Museum associations have also been working to develop standards for best practices when managing museum collections information. The Museum Documentation Association (MDA) in the United Kingdom has developed a standard called SPECTRUM that is a guide to good practice for all museums when documenting their collections.^[19] The Visual Resources Association (VRA) has established data content standards for Cataloguing Cultural Objects (CCO), fulfilling much the same purpose as the Anglo-American Cataloguing Rules (AACR2) in library and archives communities.^[20]

Data Sharing Initiatives

Efforts to develop international standards acceptable to a range of institutions have resulted in initiatives to build extensive shared collections databases. From local to national levels, collections of digital information resources organize and allow access to a variety of data from museums of all types. The Canadian Heritage

Information Network (CHIN) connects hundreds of Canadian museums into one national network, providing a searchable database of millions of museum artifacts and an extensive Virtual Museum of Canada. The Collections Australia Network (CAN) provides a portal for information about Australian museums, including a searchable index of hundreds of thousands of Australian artifacts.

When developing these shared collections, museum professionals often have the opportunity to evaluate different standards and recommend best organizational practices. During the 1990s, the Museum Educational Site Licensing Program explored a variety of issues ranging from data standards to intellectual property rights, when six museums worked with seven universities to share information resources about thousands of digital images.^[21] More recently, the Art Museum Image Consortium (AMICO) was able to use the resources of its extensive library of digital images to develop detailed specifications and data dictionaries for institutions scanning and organizing data about images.^[22] These projects frequently relied on the resources of their member institutions to test different methods for providing access to distributed sets of artifact data, and for connecting multiple museum databases while accounting for variations in data types, semantics, and query terms.^[23]

Museum professionals often form consortia to achieve the common goals of the member organizations collaborating on digital projects. Typically, these consortia are able to undertake projects of greater complexity than any one institution would be able to handle alone. Museum collaborations are usually formed to create a collective digital resource to which all participating organizations will contribute. The Museums and the Online Archive of California, for example, brings together 75,000 object records from 11 cultural institutions in California.^[24] The Collaborative (formerly Colorado) Digitization Project brings together cultural heritage materials from institutions across the western United States into one shared resource repository.^[25] The Scottish Cultural Resources Access Network has gathered hundreds of thousands of multimedia and text records about Scotland into one central repository.^[26] These cooperative endeavors testify to the museum community's commitment to finding new ways of organizing and sharing information resources.

INFORMATION TECHNOLOGY IN MUSEUMS

The first attempts to computerize museum collections occurred in the early 1960s, when several institutions began exploring the potential benefits of automating their collections management with computerized systems.^[27,28] These early systems were developed on mainframe systems and used to store descriptive information about museum artifacts. The Smithsonian Institution, for example, developed information systems, such as Smithsonian

Institution Information Retrieval System (SIIRS) and Self Generating Master (SELGEM), which were used at institutions across the country during the 1960s and 1970s. The Museum Computer Network (MCN), founded in 1967, developed and distributed a system called Generalized Retrieval and Information Processing for Humanities Oriented Studies (GRIPHOS) to their member organizations. One of MCN's first projects was to evaluate standards for information organization and access at 12 art museums nationwide, and MCN sponsored the first conference on computers and their potential applications in museums at the Metropolitan Museum of Art in New York in 1967.^[29]

Soon, a number of institutions were using mainframe systems to store data about their collections in electronic format. Museum professionals began to meet at a variety of conferences to discuss organizational standards, best practices, and new uses for information technologies in museums. As computers became cheaper, faster, and easier to use, even professionals working for small, poorly funded museums were able to purchase computer systems and database software for collections management. Vendors started developing and distributing collections management systems for many different types of museums. By the 1980s, new technologies had been developed that supported digital imaging, and museums began to experiment with building digital image databases. As the use of digital networks such as the Internet became more widespread, museum professionals found even more ways to share data about their collections. Today, museum professionals face a rapidly evolving information environment, and conferences such as the international conference of Museums and the Web and the annual meetings of the MCN help keep hundreds of museum professionals up-to-date with the latest techniques and methods of bringing museum information resources online.

Museums and Digitization

When museum professionals discuss “digitizing their collections,” they refer to a process in which two things can occur: 1) they record in electronic format descriptive data about their artifacts; and 2) they produce some type of digital representation or image of each object. These two activities are often easily confused. When museums first began working with computers, digital imaging was not even a possibility, and when museum professionals referred to “computerizing” their collections, they meant taking descriptive, textual data from their ledgers and card files and converting them into electronic format. Today, with the prevalence of digital cameras and scanners, most museum professionals have expanded their definition of “digitization” to include digital imaging, and it is easy to forget that when a collection is digitized, the museum professionals in charge of the project must do more than produce a digital image of each artifact. They must also record descriptive data about the object (such as its

provenance, classification, and composition) in electronic format, and generate new, additional metadata for the electronic object.

Recording data about museum artifacts in digital format offers museum professionals immediate benefits. These benefits include the ability to make a virtually infinite number of perfect copies of digital surrogates, and transmit them over great distances with no loss in quality; to offer new levels of interactivity between objects and users; to take advantage of hypermedia and multimedia to remove objects from the constraints of physical space and present arrangements impossible in physical galleries; to provide remote access to information resources for visitors, scholars, researchers, and students; and to target unique information needs, by broadcasting information resources to wide audiences or narrowcasting information resources to individual users.

The ever present push for digitization has created new problems and exacerbated old ones for museums. These problems include concerns, worries, or fears over such issues as copyright and intellectual property; the potential lessening of the “aura” or authenticity of museum artifacts; the blurring of individual museum identities online; and the potential impact of access to digital surrogates on physical museum visitation. The opportunities and challenges afforded by digitization have prompted new questions and concerns about the rise of the digital museum in the information age.

The Digital Museum

New technologies and online museums mean easier access and wider use of information resources that may previously have been more firmly controlled by the governing institution.^[30] Some museum professionals worry that when they digitize their collections and make digital resources available online, they lose control over the museum's intellectual property and other copyrighted materials. Such concerns have prompted some institutions to protect their intellectual property by restricting access to certain types of data or making it difficult to reproduce the content they control. For example, museum professionals may attempt to prohibit the illegal duplication of digital images by embedding visible or invisible watermarks into digital image files.^[31] These approaches are only stopgap solutions, however, and a true solution to this problem will only come when the museum community reevaluates its approaches to rights administration and content distribution, developing new economic models for digital cultural heritage.^[32]

Another question asked about digital museums concerns whether visitors will stop visiting physical museums as more information about museum collections is available online. This fear has become even more prevalent as the quality of digital artifact representations online has increased; many museums offer extremely high-resolution

images of their artifacts online, and some even offer three-dimensional representations that can be manipulated by virtual visitors and examined from all sides. With such features available online, some museum professionals wonder whether museum visitors will still bother to visit the real thing. Fortunately for museum professionals, recent surveys have provided compelling evidence that online museums actually drive physical museum attendance instead of discouraging physical visits; in the majority of studies, planning a museum visit is consistently cited as the primary reason people visit museum Web sites.^[33,34] Kravchyna and Hastings^[35] found that 57% of museum Web site users visit museum Web sites both before and after they visit physical museums. Similarly, Thomas and Carey^[36] found that 70% of museum visitors specifically looked for online information prior to a museum visit, and that 57% said the information they found online increased their desire to visit the museum in person.

Despite the potential challenges, museum professionals remain eager to digitize their collections, prompted no doubt by the growing number of museum visitors who now expect museums to provide access to their collections in digital formats. As the technologies required to build a digital collection become easier to use and cheaper to acquire, more museums have the opportunity to embark upon digitization programs, and more opportunities arise for museum visitors to interact with digital museum collections.

INFORMATION INTERACTIONS IN MUSEUMS

Museum professionals use new information technologies to develop innovative ways of reaching their visitors, online and in-house.^[37,38] Inside the museum, interactive kiosks encourage visitors to explore topics in greater depth and at their own pace. Online, virtual museums allow visitors to plan gallery tours, research artifact collections, and learn from interactive educational exhibits. New information technologies have changed how museum professionals achieve their missions, and encouraged museum visitors to embrace the new capabilities of the digital museum.

Museums and the Web

When museums started going online in the 1990s, museum professionals discovered that the Web offered them the potential to provide more than information about their museum's location, hours of operation, and brief descriptions of their collections. They began to explore the capabilities of online exhibits, realizing that increased access to digital collections offered new opportunities for interacting with museum collections and information resources.

Online museums and virtual exhibits have the potential to cover topics in ways not possible in physical museums. For example, Douma and Henchman^[39] present an online exhibit that allows visitors to digitally remove layers of a painting (Bellini's *Feast of the Gods*), examining earlier versions using simulated infrared or x-ray lenses. Gillard^[40] explores how the National Museum of American History's HistoryWired project encourages visitors to manipulate a collection of artifacts, uncovering connections between objects along temporal, cultural, and thematic lines. Sayre^[41] describes how the Minneapolis Institute of Arts allowed online visitors to follow the restoration of a painting in real time, drawing them into the process and building stronger relationships between the museum and its visitors.

Many museums offer three-dimensional interactive tours online that mimic the experience of visiting the museum in person, while simultaneously opening an array of new possibilities for interaction.^[42,43] Online museum visitors, for instance, can compare and contrast artifacts that in real life may not be in the same exhibit or even the same museum. Some institutions have experimented with live online exhibits, using webcasting techniques to interact with global audiences in real time. The Exploratorium in San Francisco, for example, broadcasts live coverage of solar eclipses (online and recently in the virtual world of Second Life) and has developed a related online resource guide (<http://www.exploratorium.edu/eclipse/>).

New technologies have also offered museum professionals ways to bring information about their collections directly to their audiences. As museums continue to digitize their collections, it has become more common for museum professionals to make their records available online to the general public. These resources are used by a wide variety of online visitors, from recent visitors interested in learning more about artifacts they saw in person, to academic researchers at distant universities searching for particularly unique specimens. As more museums develop online collections databases, museum professionals have explored the potential benefits of linking these databases directly into their online exhibits, providing online visitors with instant access to the latest collections data.^[44]

Personalization Technologies

Modern museums can personalize the museum-going experience in ways never before possible. It is now common for museums to offer handheld devices—such as audio guides—to their gallery visitors. In essence, visitors to these museums have their own digital docents that can discuss artifacts of personal interest to them, providing a digital twist on traditional museum guided tours.^[45] Using a handheld device, visitors can listen to audio descriptions of works of art, allowing them to explore the gallery's contents in any order and at their own pace.

As handheld computers become less expensive, museum professionals continue to experiment with the capabilities of these devices, offering their visitors detailed text and digital images in addition to audio tracks. Projects that explore the educational potential of mobile computing devices in museums are becoming especially crucial as more museums integrate such systems into their exhibits and learning experiences.^[46] Several projects have demonstrated the value of mobile computers for increasing visitor interactions and improving educational experiences in museums.^[47,48]

As museum professionals explore new methods of making information on collections available online, revolutionary trends in personalization have occurred in the online museum environment.^[49] A growing number of museums, including the Metropolitan Museum of Art, the Virtual Museum of Canada, and the Fine Arts Museums of San Francisco, now allow visitors to create personal digital collections of their favorite artifacts, adding or removing artifacts at will, and returning to view their collections whenever they like. Some museums, such as the Minneapolis Institute of Arts and the Walker Art Center, allow online visitors to group digital artifacts into personal galleries, annotate them with textual descriptions, and share them with other online visitors.

The future of museum personalization can be found in the application of web 2.0 and social computing technologies for online museums; the collaborative social tagging project Steve (<http://steve.museum>) provides an excellent example of how these technologies can be implemented for museums. It will likely soon be common for museum professionals to encourage their online visitors to draw new connections between artifacts, store those connections on the museum's computers, and share them with other museum visitors. In this way, museum visitors will add value to digital collections, contributing their knowledge to the museum's collections by adding new connections and interpretations across user communities.^[50,51]

INFORMATION MANAGEMENT IN MUSEUMS

Information management skills have always been important for museum professionals, who have a lengthy history of working with information resources and technologies.^[52] As museum information resources become more technically complex, and the users of those resources become more information literate, the needs and expectations of visitors have become increasingly sophisticated. Users of museum resources are no longer satisfied with limited access to information about museum collections, and many desire 24 hr access to museum data, no matter where the data are located, or how the data are organized. While the ability to manipulate and manage information resources has long been an important skill for museum

professionals, meeting these changing expectations can be difficult for museum professionals.

Changing ideas about the museum's position as an information service organization can pose difficult challenges for museum professionals, often requiring them to learn new information management skills and integrate new information technologies into their daily work.^[53] Increased access to the digital information resources of libraries, archives, and museums has driven changing expectations from all museum users, including museum visitors and museum professionals, about the information resources museums should provide online and in-house.^[54] Users of all types frequently expect digital museums to act more like digital libraries—a situation that puts immense pressure on museum professionals to live up to the changing needs and expectations of their users.

Information Professionals

Museum professionals have become increasingly concerned with the ability of museums to function in the information society, to meet user needs, and to ensure that the right information resources are available at the right time and place, inside or outside the museum. To accomplish these goals, a new role has emerged for information professionals in museums.^[55] The success of museums in the information age will depend largely on the work of information professionals trained to deal with the problems of museum informatics and the museum's information needs.

Information and communication technologies in museums change so rapidly that museums need individuals on staff who can guide them through the hazards of planning digitization projects, purchasing collections information systems, or joining online data sharing initiatives. Museum administrators know that if a museum is to participate in the information society, someone at the museum needs to be able to set information policy, manage information resources, administer content management systems, implement metadata standards, evaluate information interfaces, etc. While some technical jobs (including Web design) can be outsourced, museums that do not have in-house skills with museum informatics will find it difficult to meet the constantly evolving demands of their increasingly information-savvy audiences.

MUSEUM INFORMATICS: FROM PRACTICE TO THEORY

The future of museum informatics as a unique research area depends on its ability to bridge multiple disciplines, drawing upon disparate theories and methodologies, and connecting the traditional professional world of museum studies with critical theories from the emerging worlds of new media and digital cultural heritage. Recent

publications have been extremely influential in setting an agenda for museum informatics and providing the intellectual framework necessary for the advancement of the field as a research area, a particularly important achievement for an emerging field such as museum informatics.^[56,57]

The principal challenge facing the establishment of museum informatics as a unique research area lies in the fact that museum informatics is an extremely interdisciplinary field of study. Researchers interested in the museum's changing role in the information society have drawn upon theories and techniques from dozens of related fields, including digital libraries, human-computer interaction, social network analysis, cognitive science, museum studies, library and information science, etc. While early work in this area focused primarily on how information technologies should be used in museums, researchers are now emphasizing the need for an underlying body of theory and methods for studying museum informatics as well as related fields such as museums and new media or digital cultural heritage.^[58]

To explore new theoretical perspectives and to develop new methodologies, researchers and professionals from around the world have joined together to form evolving communities of practice, dedicated to providing guidance to museums and other institutions of cultural heritage as they address important issues in museum informatics.^[59] Interest in museum informatics is now widespread, and each year, thousands of people worldwide participate in discussions, projects, and research initiatives related to museum informatics.

Museum professionals and researchers today belong to many different professional organizations and attend a variety of conferences dedicated to exploring museum informatics, including the meetings of such organizations as the MCN, the MDA, the International Council of Museum's International Committee for Documentation, the International Cultural Heritage Informatics Meeting, the International Museums and the Web Conference, and the Institute of Museum and Library Services' WebWise Conference. The published conference proceedings from these meetings, many of which are freely available online, provide important, timely, and often extremely cutting-edge primary resources for individuals interested in studying museum informatics.

The prodigious number of museum informatics-related events (including conferences, training events, symposia, etc.) as well as their regular high attendance are indicative of a continued and widespread professional engagement in this area. In addition, during the last few years, there has been a flourishing of university programs in this area. In the United States and Europe, for example, there are educational programs where students can study exclusively in such areas as museum informatics and digital cultural heritage. These programs are indicative not only of an increase in research activity by academics, but also of the

increase in interest and demand by students for resources and publications in the area of museum informatics. To meet this demand, a growing number of scholarly journals now publish papers about museum informatics. The *Journal of the American Society for Information Science and Technology*, the *Journal of Digital Libraries*, and *Curator*, for example, have all published special issues on museum informatics. More recently, the *Journal of Museum Management and Curatorship* has added a permanent section on Digital Heritage to its quarterly issues.

While the increase in publications related to museum informatics (including books, journals, and conference proceedings) is extremely encouraging, the increasing amount of literature has posed challenges for museum informatics researchers. In particular, the natural interdisciplinarity of museum informatics (covering such topics as technology, communication studies, museology, education, information science, etc.) tends to result in a centrifugal approach to publishing, where key pieces of research can appear in very different domains, speaking to very different peer groups. As interest in museum informatics continues to rise, therefore, researchers and practitioners seeking to establish museum informatics as a research area must collaborate to bring together any and all research related to the intersection of people, information, and technology in museums—including both the practical processes and theoretical discourses that relate to the organization, management, and use of museum information resources.

CONCLUSION

The study of museum informatics requires a sociotechnical approach to information resource management in museums. New information technologies have changed the way museum professionals think about the purpose and capabilities of museums. These sweeping changes have affected the way museums manage their information resources, in-house and online, in almost every aspect. The world of museums is being altered constantly by the introduction of new information technologies, as new technologies reshape the job of the museum professional and the overall function of museums in the information society.

To understand these changes, museums must be examined as complex sociotechnical systems that evolve and adapt to meet new challenges. Museum researchers must study museum informatics within complex and interlocking organizational and social contexts affecting the nature of museums in general and the expectations of museum professionals and visitors in particular. In this way, museum professionals and researchers will be able to embrace the growing role of museum informatics in the twenty-first century museum, and continue to explore the sociotechnical implications of people, information, and technology interacting in museums.

Museum Management

Gary Edson

Center for Advanced Study in Museum Science and Heritage Management, Museum of Texas Tech University, Lubbock, Texas, U.S.A.

Abstract

Museums must address an increasing array of issues to succeed in the dynamic environment of the twenty-first century. In response to this often-daunting process, the role of institutional management has been assigned greater responsibility and often, greater liability. It must define the museum's mission, justify its legitimacy, and reconcile its relationship with changing constituency expectations. In response to this challenge, museum management is exploring the economic landscape to develop creative and sustainable institutions that serve the interests of the public while negotiating the legal pitfalls, and maintaining the ethics and standards of the international museum community. This entry addresses a number of the issues relating to contemporary museum management. It draws from the precepts of the corporate, as well as the not-for-profit communities, to stimulate understanding of the role and responsibility of inclusive management as a practical response to the complexities of the contemporary museum.

INTRODUCTION

Museums as a part of the rapidly expanding not-for-profit sector must be prepared to adjust to the changing demands. The traditional separation between the not-for-profit and the for-profit worlds is an ever-narrowing gap due to the commonly shared need for money, growth, and prominence. However, unlike the commercial sector, the museum must also conform to the ethics and standards of the professional community and a scrutinizing public. Museum management is often at the epicenter of this shifting landscape of successful achievements and unresolved challenges.

The purpose of museums continues to be service to society, the community, the public and its various constituencies, including those persons that are physically or mentally challenged. The collections are for people, whether those people are the public or researchers. Museums must retain these time-honored values and beliefs while considering escalating expenses, public demands, technology, changing demographics, mergers, outsourcing, governmental regulations, tourism, outcome assessments, and maintaining donor confidence to name but a few issues. The challenges increase exponentially for museums pursuing international interests, such as collections and exhibitions. Nevertheless, the successes are frequent enough to keep dedicated individuals engaged in pursuing the elusive quality customarily called excellence.

The Museum community has endorsed different methods for dealing with management issues in the quest for excellence. Some institutions have turned to the business community for leadership, and others have reinforced core values by relying on museum professionals and more formalized management practices to guide the institution. Both approaches demonstrate the critical concern about

museum management in these early years of the twenty-first century.

Often the management of an institution is the least considered aspect of a functional and effective museum. The popular belief is that museums are about unique, often beautiful, and usually significant cultural objects. How those objects are collected, housed, protected, conserved, and exhibited is not and should not be a concern for the average museum visitor. Nevertheless, the "life" of a museum is best represented by the activities that the public never sees, and by the dedication of numerous museum professionals that champion the care and protection of cultural and natural heritage.

This entry will acquaint the reader with a range of museum management issues, processes, and practices. The information will explore the importance of museum management and explain such topics as management structures, personnel management, teamwork and mission, financial management, management planning, and management ethics. Each of the elements is critical to a successful and sustainable museum and its continuing effort to serve the profession and the public.

MUSEUM MANAGEMENT

Museum management is an important but often misunderstood element of the museum profession. Individuals, particularly those entering or preparing to enter the workforce, normally think of museum management as that activity performed by only the director or upper administrators. Many persons associate the idea of management with the "boss." That perspective continues today, although many managers/directors consider themselves leaders instead of individuals who tell others (subordinates) what to do. All

museum personnel are involved with management in fact. Every person in a museum, regardless of title, has a position of responsibility that includes accountability, duty, and trust. Everyone should be working to accomplish organizational goals, that is, contributing to the process used to attain what the museum wants to achieve—its defined mission.

The term “management” is likely to be called “administration” in most English-speaking countries. Whereas in the French, Spanish, or Italian tradition of public service it is referred to as “*gestion*.”^[1] Although this entry will focus on that aspect of museum management (administration), many of the practices described are applicable throughout the institution. Elements such as budgeting, planning, human resource considerations, communication, teamwork, honesty, and accountability have obvious generalized applications. Museum management is an inclusive concept that involves the judicious use of resources to accomplish an objective. It is both an intellectual and a practical concept.

Museums, as public institutions, exist for the public’s benefit, and to be successful, all aspects of their operations should reflect that obligation and commitment. Management is an integral element in maintaining and promoting ethical and legal stability. Collecting, conservation, and research should be executed with a public consciousness, just as the more visible or public-oriented exhibitions and educational programming. These activities are valued elements of museum management. An organization operating in the public interest must manage its affairs properly, but museums as custodians of the cultural, natural, and scientific heritage of a people, region, or nation must function, as nearly as possible, above criticism.

Management and administration are often used to mean the same activity in many locations. The use of “management” in this way applies a collective term describing the “manager” of an organization, for example, a museum. However, management as an act of controlling something successfully can apply throughout the museum, whereas “the administration” is by definition charged with regulating the affairs of the museum. Interestingly, there is no consistent prototype for the general administration (management) of museums. This situation is usually ascribed to the diversity of museum collections and may reflect a lack of understanding of the role of museums in contemporary society. The ambivalence is the result of not knowing whether museums are guardians and interpreters of cultural heritage, repositories for the study of human and natural history, social instruments in community development, or facilities of leisure and recreation.^[2]

Museum management is commonly associated with the level of authority within the organizational structure where institutional decisions are made. The museum manager may have different titles, such as director or chief executive officer (CEO), and it is that person who normally makes decisions about the way the museum is

organized, the services it provides, and the people it serves. The manager/director is usually hired or appointed by the governing authority, and that person is vested with the authority to make day-to-day operational decisions, including the hiring and disciplining of staff. Managers/directors are expected to provide the leadership, vision, and guidance that are a part of good management.^[3]

Organizational management, including the manager/director, represents the essential nature of museum operations. It is that part of the institutional structure that acknowledges and supports the cultural, natural, or scientific experience through carefully prepared and thoughtfully presented exhibitions of collections, quality research, and an insightful plan for preserving objects for future generations.

Effective museum management at any level and in most countries does not occur in a vacuum. All museums operate under some form of governing body—board of directors or trustees, Minister of Culture, or city government. The museum should be established according to the laws of the country or state in which it exists. It should have, as a part of its documentation, a written constitution, statute, or other enabling document that states the museum’s legal and financial status. The documentation should confirm that the museum is not organized to make a profit; rather, that it is intended to serve the public need. The concept of not-for-profit maintains the idea that any income generated by the museum is intended for the support of the institution and not for distribution to individual subscribers. This idea seems simple, but the concept is sophisticated, because it includes the principle of philosophical ownership as opposed to physical ownership as found in for-profit organizations. The stakeholders of the not-for-profit organizations are the public, and the governing authority (board) of the museum that represents them. That authoritative body has fiduciary (i.e., evoking public trust) responsibility for the museum. They can make decisions and determine programs, exhibitions, and collections, but may not receive benefits as individuals beyond knowing they have acted as good stewards and responsible trustees.

(NOTE: The terms nonprofit and not-for-profit continue to cause confusion in the international museum community. Nonprofit is interpreted to mean that the museum cannot make money. Whereas, not-for-profit means that the museum is not a commercial enterprise. It is generally accepted that the latter definition is the more acceptable.)

The concepts of public service and philosophical ownership of museums are closely related. The idea of individual (personal) or board (group) ownership of museums as not-for-profit organizations should not exist. There is no physical ownership in the traditional sense because museums are intended to serve a public purpose. This notion of ownership is a very important aspect of the not-for-profit sector. The governing authority (board) governs on behalf of individuals who are not seated at the board

table. That group (board) may change and the staff may change, but the “public,” although an ill-defined entity, continues to “own” the museum as a holding place for cultural, natural, and scientific heritage.

One of the most important aspects of the organizational documentation is that it reflects the values and beliefs that initiated the need for the museum and that will sustain its continued growth. The museum may be the result of a personal or governmental vision, but that vision must be of appropriate significance to mobilize others into action as supporters and visitors. The beliefs of a museum constitute its value system that differentiates the work of a particular museum from others, or defines critical differences in approach or methods among similar efforts. The management must work to sustain belief in the museum, promote its mission, and advocate its permanence.

The defining institutional attitude that directly connects to management is the museum’s mission and policies and provides the organization, its leadership, and staff with a stable foundation upon which to build. The authority of the manager/director generally depends on the laws and regulations under which the museum is established, as well as the internal documents. The regulatory rules may differ from location to location; nevertheless, a primary role of museum management is assisting the museum in achieving consistent results so the institutional mission can be articulated and fulfilled.

The operation of all types of museums is based on teamwork, and this has important implications for the management structure. Managerial (administrative) duties are commonly assigned to the manager/director, and it is normal for that individual to guide the institution toward the desired goal through planning, organizing, directing, and controlling. These four functions of management are applicable throughout an organization. There may be one manager/director for the museum, but there are other managers at different levels. Diversified museum management is exemplified by the processes associated with accessioning and deaccessioning, inventory of collections, educational programming, exhibitions preparation and installation, preventive conservation, integrated pest management, and a continuing list of other practices common to all professionally oriented institutions. The four functions are included at each level of management, though the emphasis on each function may change. The management role fulfilled by the upper administration of the museum is a relatively small, albeit important, aspect of the overall activities of the institution.

Because museums are labor intensive and require a wide range of skills, the management duties may be assigned on different levels, depending on the size and structure of the particular institution. Larger museums may have a structural layer identified as “upper management.” This element of the museum includes the manager/director and a number of assistants (senior specialists) identified by different titles. The second layer may be

called “middle management” to identify the division heads. These managers have a specialized understanding of certain tasks such as collection management or program development. They are usually responsible for implementing decisions made by upper management as well as supervising employees. Some museums also identify a level of “lower management” that ensures the decisions and plans are executed. These managers have responsibility for tasks of limited duration and include a limited number of support staff.

It is important for all persons with management responsibilities to understand the administrative, legal, and ethical issues applying to their circumstances and the conditions relating to their work. Although these factors also vary from country to country, issues relating to import, export, or transfer of cultural property, endangered species, sacred materials, and human remains have universal implications that must be considered. These issues may significantly influence both museum management and professional practices.^[3]

Building and stabilizing an organizational climate is the crux of the concept of public trust as placed in museums. Although a museum’s management responsibilities and therefore its structure may differ, there are, nevertheless, certain elements that are common to most. These include the following:

- Purpose*—a clear understanding of the purpose of the museum in the public interest
- Program*—maintaining a program consistent with the museum’s stated purpose and its available personnel and financial resources
- Expenses*—supervising programs, management, and related expenses
- Promotion*—ensuring ethical publicity and promotion, excluding exaggerated or misleading claims
- Fund raising*—soliciting contributions without payment of commissions or undue pressure
- Accountability*—producing an annual report that describes program activities and supporting services in relation to expenses and that contains financial statements
- Budget*—developing and implementing an annual budget approved by the governing body in a form consistent with an annual financial statement

Because museum personnel other than the manager/director may be engaged in completing these tasks, management is often thought of as simply having the ability to get something done by other persons. The manager/director should ensure the museum is a professional, systematic, enjoyable, and socially conscious institution regardless of who performs a particular task. The management must understand and apply principles drawn from research and “best practices” in business and public service, as well as the museum field, to meet these various challenges.

Consideration should be given to a wide range of academic disciplines, including economics, law, psychology, sociology, and information technology.^[1] Attention must also be given to management functionality, as the action of measuring a quantity on a regular basis and of adjusting initial plans as actions are taken to reach the intended goal.

The management has a responsibility that embraces all the resources and activities of the museum in fulfilling its various duties. Effective management is the means of ensuring that a museum, regardless of its size or complexity, achieves consistent results so the institutional mission can be fulfilled. It is a necessary element in the development and advancement of a museum. Without proper management, a museum can neither provide appropriate care and use of collections, nor can it maintain and support an effectual exhibition and education program. Public interest and trust can be lost without qualified management, and the museum, as an institution in the service of society,^[4] can be jeopardized.

It may be important to gain greater insight into the way museums operate to better understand the museum management process. Who or what authorizes the museum and to whom does it (the museum) report are questions to consider. There are at least four different types of museums based on their authorizing agencies:

- Governmental—those museums that are authorized and supported by local, regional, or national governmental agencies.
- Private—museums funded and operated by individuals or private organizations. Church museums are included in this group.
- University—museums that are attached to colleges or universities and maintained for educational, that is study, collections.
- Combination—museums that were initiated by governmental agencies or private organizations and transferred to the other for operational purposes. (This type of museum may be the result of governmental change or the reduction of funding. A nongovernmental organization may be formed to provide funding for the museum to continue the museum's operation.)

The authorizing agency is generally responsible for defining the governing authority for the museum. That authority is often referred to as a Board of Trustees because they are entrusted with oversight responsibility for the museum. That board has fiduciary responsibility of the institution. The governing board (trustees) has the duty and responsibility to manage the affairs of the museum, so its property will not be diverted from the public purposes for which it was entrusted. They hire, evaluate, and when necessary fire the manager/director. They approve the budget and promulgate policies, but should leave the management of the organization to the manager/director.

It is the responsibility of the board to

- Clarify the organization's mission
- Interpret the mission statement to the public and enhance the organization's public image
- Approve goals and objectives and set long-range plans
- Establish policies and other guidelines for agency operations
- Be legally responsible for all aspects of the organization's operations
- Ensure the organization's financial stability and solvency
- Hire and support the manager/director and assess his or her performance

There are also boards that give counsel but do not govern. These are advisory boards. They may provide advice to the governing board, the director, or any element of the organization. Advisory boards can be positioned anywhere in the museum structure as long as they are attached to some element. They have only the authority assigned by the governing body. The assigned authority may be extensive or limited, but it must be retractable, that is, someone or some board must have the power to remove the authority granted to the advisory board.

Some museums have a workgroup board. This generally refers to a governing board with minimal or no staff support. Therefore, the board must govern and do the work. Small organizations may have boards with these dual responsibilities. This is not a true board type because it has no assigned location within the organizational structure. It is at the top and everywhere else. Workgroup boards have two different roles and those roles are best served when kept separated.

Governance and management are used to describe the functions or activities by which a board carries out its responsibilities. When a not-for-profit organization has a professional staff, the partnership between the board and staff occurs in fulfilling the management function rather than governance and administration. Boards provide governance and staff does the management and administration functions in theory; however, in practice, the three activities are often intermixed. When this happens, it may be a source of frustration for both the staff and the board. It compounds the issues of "who does what." This complexity is most noticeable when an organization grows and the organizational demands increase. The expansion results in unclear lines of communication, authority, and decision-making, thus causing confusion and organizational dysfunction.

MANAGEMENT STRUCTURE

It may be of value to differentiate between leadership and management before discussing the management structure

of museums. These terms are important to the organizational structure of a museum. They acknowledge different characteristics, but are often used interchangeably.

There are good leaders who are good managers just as there are good managers with excellent leadership qualities. However, the opposite is as likely to be true. A good leader is not necessarily a good manager. Managers, by simple definition, are considered experts of efficient organization planning, direction, and control of the operations of a museum. Leaders, on the other hand, are to provide a more visionary reference point for institution attitudes, beliefs, and responsibilities. Leaders set the standard of achievement anticipated by institution personnel such as trust, honesty, personal integrity, efficiency, competency, equity, and dignity. The successful contemporary museum leader is a composite of experiences, skills, and attitudes.

The abilities of the manager/director often influence the organizational structure of a museum. It is also true that a structure appropriate for a smaller museum may not be satisfactory or acceptable for a larger institution. Museums operated as part of a governmental construct may be required to function and be structured according to the management system of the governing body. There is, however, a need to maintain a proper system of operations according to accepted museological practices. A crucial matter for management is therefore to define the structure under which the museum is authorized, governed, supported, and operated. This basic procedure is valuable for existing as well as newly formed museums. Often the management structure is assumed and based on previous practices but lacks clear documentation. A simple diagram or organizational chart can be used to demonstrate lines of authority and information exchange.

The organizational structure may be viewed in different ways. The exact relationship between members of the staff often depends on the perspective of the participants and the practice of the museum. Nevertheless, an organizational diagram (also called a flow chart) is very beneficial in defining structural relationships.

The governing authority is at the top with the director/manager immediately following in the most common organizational structure. The rest of the staff is arranged below according to their relationship with the primary divisions (or functions) of the museum. This arrangement is known as a *hierarchical structure* (Fig. 2) and is an authoritative or top-down approach to institutional management. A second arrangement, often called a *horizontal (or flat) structure* (Fig. 3), spreads the line of contact with the director/manager to give all staff equal access. A third organizational configuration that can function very successfully is the *matrix structure* (Fig. 4). All elements ultimately converge on the director who is the link between the governing authority and the staff regardless of the structural arrangement. The structure may vary, but it should be clearly defined, and care should be taken to involve staff in a range of decision-making roles. One way

to promote this exchange is to have a management advisory committee (team). This arrangement allows members of the staff to meet regularly with the director/manager and to discuss issues related to operational activities.

Although certain organizational structures are common across the museum community, each institution by its unique nature has a structure that has evolved over time to meet the particular needs of that institution. The structure of many museums gradually flattens to allow greater access to the director/manager. The more centralized the decision-making authority, the more likely the institutional structure will gravitate in that direction.

A variation of the matrix structure is becoming more common as the museum staff becomes more diverse. Fundraising, marketing, and community engagement personnel often require a coordinated focus group (or committee) that must follow a specific agenda. Fund raising, for example, must establish a systematic process for identifying, developing, and soliciting donors. This process is time consuming and requires intensive communication between members of the team. The team may expand or contract depending on the leader's assessment of a particular project and the approval of the manager/director. Other activities within the museum may be equally well served by using a matrix structure. Communication is a primary factor in organizational structures, but with the matrix structure, that importance increases. The seeming autonomy of the team should not result in unilateral decision-making and unauthorized actions.

Most museums have a management structure that includes at least three components—administration, curation, and operations—regardless of the visual representation that structure may take. All elements of the museum may be the responsibility of one person, or they may accommodate many people. The tri-parted structure allows distribution of various tasks. The division of curation and operation activities is generally based on the concept of collecting and noncollecting areas. This relatively simple structure can be expanded to facilitate increased activities while maintaining clear lines of communication and an easily comprehensible reporting procedure.

The structure may be as simple as the diagram in Fig. 1, or it may be complex with a range of primary, secondary, and tertiary positions, as shown in Fig. 2. Education and exhibitions are often under operations as noncollecting elements of the museum. Budget oversight, fund raising, public relations, and marketing are often a part of institutional management reporting directly to the manager/director. The important issue is to have a clearly defined structure. All museum personnel should know where they fit into the organization and their relationship to other staff members. The organizational chart is a map that defines the system and describes the flow of museum work. It demonstrates the organizational attitude of the institution.

Fig. 1 This diagram shows a simplified *hierarchical* management structure that divides the museum activities between three basic functions. The division is between collecting and noncollecting areas of the museum.

The museum management methods and structures tend to reflect the prevailing practices of national organizations, concepts of business, and levels of development. The management structure of the museum should promote teamwork, communication, and an endorsed sense of purpose regardless of these influences. It is important, in any structure, to have personnel who have adequate experience and training to fulfill the needs of the museum or heritage organization and its stated mission.

The horizontal or flat structure (Fig. 3) is most common in museums where there is a small staff (team) and a shared workload. It has a number of advantages and disadvantages. The staff has greater access to the manager/director, and consequently, this arrangement is popular with the museum personnel. Direct communication with the manager/director has distinct advantages for individuals; however, institutional communication can suffer. Care should always be taken to ensure that there is the circulation of critical information to all parts of the museum.

The third organizational structure found in museums is the *matrix* (Fig. 4). This configuration utilizes many of the

same principles as those used in project management. The matrix structure assigns duties to unit leaders and a team of staff members qualified to address a particular task. The team may be responsible for developing an exhibition, designing a gallery, or formulating a fund raising plan. Membership in the team may extend for the entire project or for a specific part, such as the developmental stage. The matrix organizational structure may have overlapping elements that add to the exchange of information and the utilization of personnel.

LEADERSHIP

Museum management must include the issues of identity and leadership development. Consistent with the process of leadership development, museum personnel in many locations are seeking institutional identity based on preservation and dissemination of the cultural patrimony that characterizes the character of the host community. The process of patrimonial protection is ongoing and constantly evolving in a layering process of institutional awareness. Heritage preservation challenges museum identity because it is a form of social consciousness dedicated to communication and eventual understanding in the sense that it is the foundation for redefining the common wealth of humanity.

The issues of museum identity and leadership are of great immediate concern. There are few challenges that a museum must deal with as critical or as immediate as identity. Visitorship, funding, collections, social and cultural affiliations, conservation, and education are but a few of the most obvious issues to be considered within leadership and identity equation. The question of identity as a management issue is fundamental, and includes concerns about the guiding principles for museums as they address decreased funding and increased social and political expectations.

Fig. 2 This is an example of a more complex *hierarchical* structure that includes a second and third layer of museum personnel. The structure can be expanded to include any number of positions.

Fig. 3 Example of a horizontal (flat) organizational structure. In this arrangement, all members of the museum staff report directly to the manager/director.

Museum management is directly influenced by the manager/director/leader that often comes from within the ranks of the museum. However, theories about leadership maintain that traditional dependence on paternalistic rule (or materialistic as the case may be) based on status, birth, property, charisma, and power (the so-called “great man” or “great woman” theory of leadership) has been replaced by the less arbitrary measure of knowledge and ability. Although this approach was first advocated many years ago, it appears to remain true during the first years of the twenty-first century. However, this so-called leadership model has evolved at different rates in different part of the world. Privileged leadership continues to be

Fig. 4 Matrix organizational structure. Each part of the matrix structure has a level of autonomy, that is, it has a project or activity to accomplish. The team leader or project manager oversees and coordinates planning and resources. The team leader is a facilitator that encourages communication, sees that information and resources are available, calls meetings, and assigns tasks. The team leader reports to the manager/director. The number of teams deployed depends on the needs of the museum and the availability of qualified personnel.

accentuated and implemented by the issues of status and power as epitomized by political appointment. This practice is resident in many locations and is often detrimental to the museum community.

Wise leaders established management teams that balanced the ideas, attitudes, and aspirations of its members to accomplish the stated institutional mission. Early in the knowledge-based leadership process, it was assumed that expertise was the critical factor in effective leadership. However, it was quickly determined that intellect alone was not sufficient to make someone an effective leader. Instead, a participative leadership style that allowed team input in decision-making proved more effective.

PERSONNEL MANAGEMENT

Established values and beliefs drive the museum, good management makes it operate efficiently and effectively, and strong collections give it identity and creditability. Nonetheless, it is the personnel, paid or unpaid, who makes the museum a meaningful and functional place. People generate the activities that other people attend (Fig. 5).

Probably the single most defining characteristic of a nonprofit organization is the people who work within it. The role of the staff is to implement board policy, supervise museum activities, maintain the facilities, manage and recruit volunteers, and handle public relations.^[6] However, national laws and the regulations of the country in which the museum is located usually determine the rules and policies regarding employment and work conditions. The employing ministry or other governing authority may also control employment practices, and these regulations may vary greatly from country to country.^[7]

Though there is no standard approach for successful personnel management, most criteria are based on cultural assumptions about what such practices should entail and how they are to be achieved and implemented. Regardless of the museum’s location, good personnel management requires 1) selecting the right person for the job, 2) determining the work to be done, 3) deciding the way the work is to be accomplished, and 4) managing the relationship between the person doing the work and the other elements

Fig. 5 The inflow and outflow of people involved with the museum.

of the museum. These activities may be accomplished either directly or indirectly, depending on the size and scope of the museum. They are, however, fundamental to the management process.

A primary concern when dealing with personnel issues must be attitude. Attitude is defined as a “way of thinking” that exists in an individual and the workplace. Attitude is a major factor for museums. This attribute is reflected in intangibles such as research and education, as well as the study, care, use, and maintenance of the collections and, perhaps most specifically, in public trust. Personnel that cannot be trusted to invest in the ethics and values of the museum should be trained or redirected. Museums must be value driven. This calls for an attitude of dedication, honesty, and openness. It is a very simple concept. Institutional core values are those qualities that cause people to share their treasures and cause them to support the museum with their participation. Trusted measures are identified with values, and values are identified with trusted museums. Every museum employee and volunteer is a part of that value system.

VOLUNTEERS

Personnel management often includes volunteers used to fill the vacancies in the museum’s workforce. Certain services make effective use of volunteers in areas such as classes for children, sales in the museum shop, or housing of collections. Volunteers may also be lawyers, accountants, contractors, teachers, scholars, entertainers, and a range of other persons with specialized skills who contribute their time and effort to support the museum. Volunteer services are so important for some museums that without them, the museum would have to limit its activities.^[8] The people working in the museum, whether paid or volunteer, are one of the institution’s most valued assets.

The volunteer cadre may also include docents used to guide groups through the museum’s exhibitions and teach visiting school classes. These docents should be thoroughly prepared for their duties by the museum staff or a volunteer coordinator. The docent should receive training in all subject matter in which he or she will have to be informed, as well as the teaching of children within the museum context. Such training requires a commitment on the part of the volunteer, as well as a decision on the part of the museum that docents are an important and valued addition to the staff. A rule to remember in using volunteers is that their training and supervision should not take more professional staff time than will the work that the volunteers perform.^[8]

TEAMWORK, MISSION, AND POLICY

Of all the factors that contribute to sustained success in museums, one of the most important is creating a cohesive

and effective team. Sustaining such a team requires leadership, vision, and a commitment to the value of team effort. The most powerful function of an effective manager/director is that of inspiring others to be part of the team. The transfer of power from one or a few to many involves the delegation of tasks and the sharing of responsibility. The museum with its teams that have “equal value” is a shift in the traditional museum context where authority was vested in a few highly placed individuals.^[9]

In addition to selecting qualified personnel, good museum management builds teamwork, develops the institutional vision, and creates an environment where others can work effectively and efficiently to meet institutional goals. Team building extends beyond the museum’s administration (manager/director/CEO) office. The manager/director keeps all persons involved and feeling appreciated, so they contribute their best efforts for the good of the museum. Every member of the staff should have a meaningful role in making the museum a successful contributor to the constituency it serves.

Beyond being good practice, teamwork encourages open communication and reduces misunderstandings. As a result, individuals work toward and accept new ideas. The potential for change is heightened and institutional renewal is stimulated. An environment of openness and mutual respect is a hallmark of good management. Management fails when the manager/director loses sight of the mission of the museum, and instead becomes obsessed with issues related to the organization as an entity separate from its purpose. The possibility of this myopia is reduced when team attitudes guide institutional thinking.

A basic element of management and team building is trust, and it is more than a notion of legal or ethical action. Trust is the foundation of positive relationships, both inside and outside the museum. It facilitates a sense of intellectual and emotional security based on mutual respect, honesty, and loyalty. Trust promotes open exchange, constructive assessment, and creative achievement. These elements influence the ability of a museum to accomplish its goals. A shared commitment to respecting individual qualities, maintaining open communication, and promoting the institutional mission is essential for a functional, forward thinking, and professionally oriented museum.

MISSION

Every museum needs a mission regardless of its financial and service orientation, that is, a direction to which all its functions are dedicated. The mission is the heart of the museum’s existence. It must be a proactive indication of the organizational intent, and as a ubiquitous statement of mission, it must be endorsed and advocated by the management and staff.

A good mission statement is one that is sufficiently broad to encompass the many possible activities in which the organization may wish to engage and is adequately focused to give proper guidance. This type of broad end statement is philosophical. It results, at least in part, from what the board, staff, and volunteers believe, the world should be, and how the museum complements that perspective. This statement derives from the “idea” of “mission” as a strategy and a commitment. It verifies what the museum is about and what human needs it addresses.

A mission may be a short statement about how a museum wants to be (what it is) and how it wants to be viewed by its audience. Or, it may be the broadest expression that accurately defines the most global ends statement for the organization. It can be brief or broad but accurate and true to ends (outcome) attributes. It should not be a statement of how the organization wants to be or to be seen, but a statement of how the world will be different due to its existence.

It is normally more difficult to identify and articulate the mission of a not-for-profit organization and consequently to develop criteria by which success can be measured.^[10] A mission statement is only valuable if it gives some specific guidance on the direction the organization should take in regard to programs, services, and activities. It should be an announcement of the results to be achieved, and a constant reminder of the museum’s purpose.

A mission statement is a basic document for all museums as a declaration of purpose, and policies provide the means for achieving the goals of the institution. The governing authority guided by management and staff normally formulate policies, and persons inside and outside the museum should have easy access to these documents. Policies that address specific museum issues should be written to accomplish two primary goals. They are 1) to plan a course of action to influence and determine institutional decisions, actions, and other matters, and 2) to define a course of action for the museum that is considered expedient, prudent, or advantageous.

POLICIES

The governing entity (board) must state what is expected of themselves, the manager/director, and the staff in the policy form of management. When the policies are well formulated, the manager/director knows their limits and the staff is free to pursue institutional objectives within the established parameters. The management should formulate three types of policies:

- Philosophical
- Resource development
- Working

The philosophical policies address ethical issues, resource development policies define allocation of major resources, and working policies are concerned with operational matters. In many organizations, the management generates the first and second types of policies, and the third is staff produced. However, in forward-thinking museums, staff input into the policies regarding ethics is essential, and fund allocation without staff support is often nonproductive. If policies are designed to meet specific needs, then the persons most qualified to identify those needs are the individuals with a detailed knowledge of the organization—the staff. Nonetheless, policy recommendations may emanate from any level of the organization.

Policies are essential to good management. They will undoubtedly differ depending on the institutional mission. However, it is important to establish consistent policy documents that reflect the values and beliefs of the museum and the expectations of staff, as well as define collections’ care and use, fiscal matters, physical plant use, and other issues that directly impact upon the ability of the museum to fulfill its mission. Well-defined policies outline the framework in which management and staff can operate and help them make proper decisions. Policies also reassure the public that an institution has given careful consideration to its actions.

FINANCIAL MANAGEMENT

A significant element of all management systems is fiscal accountability. Most museums are subject to a governing authority that determines the financial practices of the institution. The authority may differ and the level of financial oversight may vary, but few museums have complete and unrestricted control over all aspects of their finances. Regardless of the level of flexibility or the source of funding, museums have an obligation to be accountable for the money allocated (given) to them. The process of budget development, fund accountability, and financial planning is generally described as financial management, and while the governing authority may carefully structure the guidelines, the implementation rests with the museum manager/director and subsequently with the staff.

Museums generally use the cash accounting method (instead of the accrual method) for maintaining financial records. Using the cash method income is not counted until the money is received, and expenses are not counted against the budget until they are actually paid. This process differs from accrual accounting in which a transaction is counted (entered into the financial record) when a pledge or commitment is made regardless of when the money or service is received. Likewise, the museum will not record an expense, in cash accounting, until all parts of a project are received, completed, and billed.

Financial management is viewed by many as one of the most difficult aspects of museum management. In reality,

the difficulty usually resides in the usability of the budget document. A budget in the simplest terms is a management tool stated in numbers. It is a planning document. Budgeting is more than balancing expected revenues with expenditures. It indicates the money available, the money needed (by projection), and the difference between the two. It also allows management to determine the most appropriate alternatives for resource allocation. A budget, in most instances, is a statement of intent that is used to guide an institution's activities. It empowers museum management to decide how to use financial resources most effectively.

The relationship between the mission-oriented goals and financial resources is critical, and budget formulation is an integral part of the planning and management process. Actual spending and receipts can be tracked against planned targets as an instrument of managerial control. Variances between expenditures and the projected budget may signal the need to slow spending or increase income, or to shift resources from one category or financial commitment to another. Differences in spending or in revenues that are more than incidental departures from the planned amounts require the management's attention.

FUNDING SOURCES

Most museums receive income from different sources. Primary support in many locations comes from the governing authority, but even in those cases, additional income may come from admission charges, the museum shop, donations, or food service. Museums have several financing opportunities:

- Admission charge
- Museum shop
- Food service
- Marketing
- Tourism
- Gifts
- Voluntary contributions (donations)
- Corporate sponsorships
- Publishing
- Travel tours
- Membership
- Grants

The financial prospects are often dependent on the imagination, commitment, and work of the management in coordination with the governing authority. An analysis of the museum's mission, location, collections, programming, and other assets will give an idea of the funding potential of the particular institution. Not every museum has every financial opportunity, but most museums have several possibilities. Care should be taken to determine

possible restrictions or prohibitions by regional or national rules before initiating nontraditional financial schemes.

The ultimate gauge of good financial management is the quality of the service provided and the relevance of that service to the museum's mission. The budget must therefore relate to the mission and the money should be used to further that mission. In formulating a budget, museum management should consider two distinct principles: 1) use established policy as a guide to planning and projections, and 2) make efficient use of funds by carefully considering how much things cost and how the money is obtained.

It should be acknowledged that budgeting is an ongoing process. It is not something done once a year and ignored the rest of the time. A budget is a working document that should be reviewed monthly by the manager/director, the appropriate staff members, and members of the museum's governing authority. This scrutiny is important because neither income nor expense can be predicted with total accuracy. Regular review is the only way museum management can know its financial standing.

MANAGEMENT PLANNING

Planning is critical to successful museum management. It is vital for all museums as a basis for supervision by the governing authority, sound management by the manager/director and staff, effective fund acquisition and utilization, and meaningful program evaluation in fulfilling the museum's mission. Every museum can be improved, and effective planning is an integral aspect of the improvement process.^[11]

Museum planning should be an inclusive activity that considers the museum's history, mission, collections, staff, facilities, funding, community support, audience, political status, local and regional problems, and other environmental and social potentialities for making decisions that will guide the museum into the future. This planning process allows the museum (management and staff) to assess, redefine, and implement its mission, programming, exhibitions, and the audience served. There is a close connection between the planning process and marketing because the planning must precede the marketing, and the marketing analysis of a museum is a part of the planning process.

Planning may include any or all of the following:

Finance/revenue: These are issues related to the current and future funding needs of the museum and its ability to secure sufficient resources to support activities for the execution of its stated mission.

Community needs and involvement: These issues refer to changing community needs and the museum's ability to develop effective responses appropriate to its mission and priorities.

Human resources: These issues concern the recruitment, training, and retaining of sufficient qualified personnel with adequately diverse backgrounds to fulfill staff and volunteer service needs.

Organizational/structural: These issues evaluate the museum structure to determine the best configuration to meet current and future museum and community needs through the provision of quality, cost-effective services.

Communications/visibility: These issues ask how the museum can make itself more visible and inform the public about its mission and services and consider what resources will be needed to execute the processes of gaining greater visibility.

National agenda: Assuming the museum is part of a national group, the institutional agenda should support increased awareness and advocacy of national issues such as funding, accountability, and standards.

Service effectiveness: These issues relate to evaluation of services, programs, and exhibits and the results to measure museum effectiveness in meeting the needs of targeted populations, and ensuring that marginal services will be enhanced or discontinued.

A museum should undertake planning to reaffirm or to modify its mission—why it exists, what its purpose is, and what it does—and to agree on its vision—what it wants to be and do in the coming years. The ultimate product of the planning process is a guide to govern the activities of the museum. It is not the purpose of the plan to decide what should be done in the future, but to decide what should be done now to make desired things happen in the future.

For museums, planning is essential to success; however, flexibility, adaptability, and creativity are elements of the planning process that must be carefully considered. This does not mean changing the museum's mission in response to social or financial opportunities. The traditional practice of relying on a five-year plan, however, is no longer practical because the cultural, financial, political, and social environment changes rapidly. The successful adaptation to change requires establishing a stable means for the museum to accomplish its mission, despite challenging external or internal conditions.

Elements of the museum that should be considered in the planning process are the following:

- Mission
- Organization
- Decision-making
- Fund raising
- Resource allocation
- Performance evaluation
- Organizational effectiveness

Financial planning is an integral part of the planning process of museums. The allocation of resources is a

significant element in setting organizational goals and fulfilling them. Depending on the needs of the museum, budget planning will assume varying degrees of importance. However, in all cases, considering the financial realities of the organization will play an important part in the development of a strategic plan.

The development of a financial plan may extend far into the future, and in all cases, it is an ongoing activity. Financial planning as a process implies intentional preparation for the future and must promote growth in a rational and achievable way. Budget and financial stability must be a part of all planning. A careful look must be taken at the feasibility of proposed services, programs, and exhibitions, not to mention staff and facility expansion. One of the most difficult elements of financial planning is projecting future income. This is an area where good information and experience cannot be underestimated.

Without planning, the organization's effort will be haphazard, the outcome unpredictable, and the management indecisive. Planning should focus on achieving the most appropriate connection between a museum and the environment in which it operates. The environment means those conditions that exist both inside and outside of the museum that have a say over its operations. Effective planning deals with the issues that develop along the margin between the inner workings of the museum and outer influences. Planning should delineate a strategy for success.

It is the governing authority's responsibility to see that planning takes place. The staff can encourage planning through the director, but ultimately the board (trustees) must start the process because, it is responsible for the welfare and effectiveness of the museum. The board, therefore must not only assure planning takes place and oversee the process, it must actively participate in the process.

SELF-ASSESSMENT

Information is an important part of the management of any organization, and to be of value, the information must be based on evaluation and assessment. Proper decision-making requires dependable information gathered in systematic ways. An assessment can be conducted on the entire institution, as with the accreditation self-study, or it can be used to assess one aspect of the museum such as financial development, public relations, and marketing, or volunteer involvement.

Self-assessment is a part of planning and one way to determine the effectiveness of the museum and the method for deciding the value or purpose of the institutional mission. Planning is a process through which a museum may

Identify needs in society

Define its relation to the mission of the museum

Evaluate its capabilities as a museum
 Assess its external environment
 Set objectives for the museum
 Select strategies for the museum
 Design programs for the museum
 Determine a budget for the museum
 Evaluate performance of the museum

A part of the assessment process is called environmental scanning. Environmental scanning is a means for the museum to systematically examine and compile data on the factors that are significant to the organization today and in the future. Centralizing this information will help the museum to understand the realities that are a part of developing the strategic plan. This process looks at the activities around the museum to determine influencing factors that may alter the future of the organization in a positive or negative way. Most of the time, these influences are monitored in an informal way. It can be very beneficial to the museum to look carefully at factors that have an impact upon the following areas:

Economics
 Legal or regulatory
 Politics
 Technology
 Society
 Demographics
 Competition

PLANNING METHODS

Planning is a necessary element of every museum. The collecting plan defines the objectives of institution collecting. A collection management plan (or policy) addresses a range of issues related to collection care and use, including accessioning, deaccessioning, loaning, cataloging, exhibiting, conserving, and storing objects and specimens. There are also exhibitions, financial, marketing, long-range, human resources, and strategic planning that must be considered.

In preparing any institutional plan, it is essential to be clear about who are the intended recipients of this documentation. It is often the expectations of this audience that will determine the type and structure of plan that is appropriate. For example, the requirement by government, or local authorities (city or nation/state) for museum strategic plans may differ from the information gathered for the internal document. (It is often the case that what government bodies require is something more akin to a business plan.)

A strategic plan, regardless of the format, is the result of careful and extensive research and strategic thinking by the museum. It is a disciplined effort to produce fundamental decisions and actions that will shape and guide

what a museum is, what it does, and why it does what it does.^[12] Strategic planning is important to museums as a basis for strong governance by the board, sound management by the executive and staff, effective fund raising by both the board and the staff, and constructive program evaluation by all participants in fulfilling the museum's mission.

There are various ways to develop a strategic plan. The two most common planning processes are the "goals approach" and the "vision of success approach." Each of these methods has a different anticipated outcome, but either may serve as a starting design for the museum.

The goals approach is a commonly used method for planning. That process requires the museum to establish goals and objectives for itself and to develop strategies to achieve the anticipated outcomes. This approach can be effective if there is general agreement on the established goals and objectives, and if those goals and objectives are adequately detailed to guide the development of strategies. This process is most effective when there is a hierarchical management structure with leadership that can establish goals for the museum.

The vision of success approach is another recognized form of planning. In this approach, the museum develops an "ideal" picture of itself in the future as it successfully fulfills its mission. This approach is most usable when it is difficult to identify strategic issues directly or if no specifically agreed upon goals and objectives exist. The vision approach is also effective when drastic changes are necessary, and the development of future achievement can provide the concepts that enable organizational members to identify necessary changes.

A commonly used method for analyzing the institutional assets is called SWOT.^[13] This technique calls for an examination of the institution's strengths, weaknesses, opportunities, and threats. It is a process and not an end unto itself. It is, however, an effective method for gathering information to be used in the planning process.

In initiating the planning process, it is not necessary to have a consensus. Different ideas, approaches, and unique viewpoints are good as a starting point for museum analysis. This kind of self-assessment should be an ongoing part of the planning and management activities of the museum.

MANAGEMENT ETHICS

No profession can survive without a body of ethics as the dynamic principles developed to reflect a changing environment. Comprised of ideals and values that guide individual and group conduct, ethics can be defined in terms of these two groups. Individual ethics are "value statements," such as rules, positions, and inferences, which incorporate ideas such as good and bad, and right and wrong.^[14] Group ethics include customs and codes that monitor an individual's behavior for the benefit of a group. Ethical

Fig. 6 Ethics is a body of correct actions that reinforces the concept of the museum as a trusted resource and the means for recognizing the highest common good. The worth of an activity is not derived from the purposes it seeks to achieve, but from its being in accordance with a policy that respects a code of ethics. **Source:** From Edson.¹⁶

theory involves how people see reality, why they associate “value” within it, and how they respond to it.^[15]

Ethics seeks to establish principles of right behavior that may serve as action guides for individuals and groups (see Fig. 6). The activities an individual, manager/director, or staff member, performs consciously and willingly and for which that person is responsible (accountable) are within the domain of ethics. Therefore, ethical concerns ought to be common to all areas of the museum. It is naïve to assume that ethics is the responsibility of the management (administration or board of trustees) and not that of the general workforce. Ethical reasoning is a part of every decision, and is fundamental to interaction with other members of the museum profession and the public. Every act or action associated with the museum profession has a related ethical matrix (Fig. 7).

Ethical responsibility is evidenced by interaction inside and outside the organization and the way a museum conducts its activities. An ethical museum is one in which all participants acknowledge professional standards and

Fig. 7 The relationship of attributes to conduct. **Source:** From Edson.¹⁷

where those principles are exemplified by the museum’s activities. The public perception of a museum’s ethical correctness (trust) revolves around its collections’ stewardship, as well as its dealings with fiscal and institutional accountability. The numbers of ethical issues related to museum management are increasing, and they go well beyond the traditional concerns for use of collections and money. There are also national and international laws that influence an increasing array of museum activities regardless of the museum size or location. Museums should have policies that delineate organizational rules and responsibilities, as well as to guide the manager/director in management duties.

Ethics is more than following the rules. It is a holistic endorsement of doing the right thing. A code of ethics is a part of the process of creating and maintaining an ethical institution and ensuring proper management. However, it is only a part of the equation. An ethical museum is one in which all participants acknowledge the core values such as loyalty, honesty, integrity, respect for others, and pursuit of excellence, and where those values are promulgated in the context of the museum’s mission.

CONCLUDING COMMENTS

Museums, as institutions in the service of society, are a reflection of the high level of social development enjoyed in many areas of the world. They require personnel (management and staff) with varied educational and decision-making backgrounds. The balancing of these efforts result in a properly functioning museum. The modern museum must be an informative, professional, systematic (in its collection care and planning), enjoyable, and socially active institution. To meet this challenge, management must include the application of practices developed by research, economics, law, education, and physical plant management combined with the latest technology. The exact arrangement of these elements in an effective model may change, but the concern for the management process enjoys equivalent importance in most locations.

Working in a museum involves public trust and entails great responsibility, including steadfast personal integrity. Ironically, the role of the manager/director with all its responsibilities and obligations is among the least well-defined positions in the contemporary museum. This impreciseness reflects the wide range of managerial duties that include the technological, political, and social capabilities required to manage and lead a museum in uncertain and demanding times. The manager/director must be a public representative, service advocate, and museum professional capable of securing essential resources for the museum while maintaining the integrity of the institution. The manager/director must have the scholarly and administrative skills to promote the mission of the museum, as well as the ability to explain critical issues that may not be

understood by the public. No job description can completely describe all the variables that might be encountered in museum management.

Because management is accountable for the way the museum conducts itself, it should be inspired by a high standard of public service and ethical conduct. If those ideals are overlooked or ignored, the museum will cease to warrant public trust and support. Conversely, a museum guided by proper management will establish the identity of the institution with reference to the social and cultural environment, and position it for future growth and influence. It is certain that a museum cannot survive without a sense of growth, identity, leadership, and vision. Management is therefore about the future of the museum and the people associated with that institution.

The contemporary museum evokes a feeling of prestige and a sense of pride that inspires and reassures visitors. It grants a measure of certainty in uncertain times. The value of a museum is in direct proportion to the services it gives to the emotional and intellectual life of the people. Proper management by an individual dedicated to serving the interests of the public, protecting cultural and natural heritage, and promoting goodwill and understanding will ensure that trust is not denied.

Museum Registration and Documentation

Dixie Neilson

University of Florida, Gainesville, Florida, U.S.A.

Abstract

Keeping documentation on museum objects is vital to good museum management. Important policies such as the Collection Management Policy that enumerates what and how the museum will collect objects, and the museum's code of ethics that defines acceptable behavior of staff, boards of directors, and volunteers provide the framework for long-term museum management. Records of accession and deaccession procedures contain specific information on the objects, their donors, and the reasons for their inclusion in, or removal from, the museum collection. Documentary files contain sections on appraisals, condition reports, correspondence, deed of gift or purchase information, notes, and shipping records. Records of loans to and from the museum are important historical documents and contain details of condition reports, photography, loan agreements, shipping details, and correspondence between parties. All files should be kept in perpetuity and preserved through the safeguards of backup documentation, protection from hazards, and deterioration and destruction.

INTRODUCTION

Museum collections are comprised of more than objects or specimens, also included are the documents and data pertaining to the objects. Documentation consists of official and legal transactions such as accessions records, loan contracts, field notes, scientific analysis, and deaccession records. Museums must establish recordkeeping procedures as a matter of responsible collections care; without supporting documents museum objects would be worthless. Keeping information relating to the collection (including any objects that may be loaned to the museum or be housed there for any reason) is one of the primary duties of the registrar. Records concerning permanent collection objects are deemed to be a part of the museum's collection and equal in stature to the objects to which they pertain; their importance cannot be overstated.

The goal of this entry is to introduce the topic of museum registration, particularly as it pertains to recordkeeping and to fully describe the collections documents and how to house them in a responsible manner. A brief background of the history of registration assists the reader in understanding the transition from early museums where the function was merely to display objects and was purely curatorial in focus, to the museum of today as educational institutions with vast resources that detail not only the object, but its place in our cultural history.

Important policies and documents under the control of the registrar are discussed such as Collections Management Policies, Codes of Ethics, and creating the documentary files for Accession and Deaccession and Loans. Philosophical and legal reasoning is offered to explain and inform each topic.

HISTORY OF REGISTRATION

The Museum at Alexandria, founded by Ptolemy in the third century B.C. may have been the first institution to use the term museum, meaning "seat of the Muses," but with a group of scholars and a library, it was more of a philosophical, educational organization. The Museum was the name given to a collection of objects owned by Lorenzo de' Medici in fifteenth-century Florence. Even then the term referred to a concept of comprehensiveness more than a building. By the seventeenth century Europeans were using the term to describe collections of curiosities. The Ashmolean Museum, built in 1683, housed the collection of Elias Ashmole and is considered the prototype of museums as we know them today.

Museum personnel in the earliest times were trained in a specific discipline and knew little of the larger concept of the museum as a whole, or its place in society. The apprenticeship nature of early training of museum staff gave little opportunity for the introduction of new ideas or methods, and the growth of museology, or museum studies as we know them.

When the Tammany Society of New York City opened its American Museum in 1791, it promised that all donations would be accepted, and the generous donors' names would be inscribed in a large register, a book kept just for that purpose. The duties of the "Keeper" of the museum included recording presents given to the museum and insuring that no visitor remove or injure any of the articles belonging to the museum. Thus the concept of a staff member dedicated to the care and control of objects was confirmed.

In 1880 Steven C. Brown was named Registrar for the United States National Museum that would become the

Smithsonian Institute. His duties included shipping, storage, accessions, recording of objects, and the distribution of objects and specimens.

Henry Watson Kent addressed the 5-year-old American Association of Museums (AAM) in 1911, and presented a complete procedure for accessioning articles. By 1925 John Cotton Dana had described various staff descriptions as he schooled apprentices at the Newark Museum. The registrar would be responsible for receiving and recording accessions, labeling, creating storage lists, filing and maintaining documents, care of photographs and negatives, inventories of book collections and in particular, the care of objects on exhibition.^[1] Thus began a transition from the arenas of display with vague practices and few rules, to professionalized institutions honoring and preserving the country's cultural heritage. Emphasis on training led to industry-wide standards of care and responsibility. Some formalized instruction through public education furthered professional development. By the second half of the twentieth century, post-World War II Americans looked to museums as a popular leisure activity. In response, widespread training programs for a variety of museum staff positions began in earnest.

In 1977 the Registrars Committee was recognized as an official Standing Professional Committee of AAM.

The mission of the Registrars' Committee (RC-AAM) is to give assistance to the AAM and its regional associations in their objectives of sound professional preparation and promotion of high standards and, specifically, shall endeavor to increase professionalism among museum registrars through educational programs and publications, establish standards of professional practice, and create an atmosphere of understanding and respect, of communication and cooperation among registrars, between registrars and other museum professionals, and between registrars and individuals in related service fields.^[2]

Registration Today

Today the duties of the registrar still resemble the earliest models, but with many additional responsibilities. At the same time they also have new tools to assist them. In particular the computer has enhanced collection management care. It facilitates many tasks such as generation of reports and compilations of collections formerly done by hand. Software programs exist to assist museums of any size and budget and have truly changed the way museums conduct much of their business.

A registrar oversees the operations that affect collections and manages risk, space, information, and people. It is generally recognized that museum collections are comprised of more than objects or specimens, but also of documents and data. Documentation consists of official and legal transactions such as accessioning, the process that makes the object property of the museum,

deaccession records documenting the removal of objects from the collection, loan contracts, donor and artist information, field notes, scientific analyses, business archives, and factual information about the objects. The term "Collections Manager" is often used interchangeably with "Registrar" to describe registration duties, literally the person who manages the collections held by the museum. Our focus, however, is on museum documentation therefore the term registrar, one who records and preserves collection information as a part of collections care, will be used in this entry.

MUSEUM DOCUMENTATION

Several types of documents are common to most museums no matter their size. While each museum may design and create their own documentation specific to the needs of their discipline, much of the content is common to all museums. Museums record their standards and practices in their incorporating documents. Writing policies, some relating to collecting and exhibiting museum objects, and others which inform the ethical behavior of the director, staff, board of directors, and volunteers, are now common practice and required for accreditation by the AAM. Files related to legal ownership of every object in the collection, and exhibition files spanning the history of the museum are important parts of a museum's documentation.

Policies

The best policies are created by a team made up of appropriate staff members so that each department's needs and individual concerns may be discussed prior to policy being set. Ethical considerations as well as the physical mechanism for carrying out these policies should be discussed and understood by the staff. New hires should be given copies of relevant policies so all staff stay current with procedures within the museum. While there are many policies that may govern a museum or a department within a museum, two in particular are considered key by AAM for every collecting institution, the Collection Policy and the museum's Code of Ethics Policy.

Collections management policy

Vital to good museum management is a written Collections Management Policy. A Collections Management Policy defines the direction of collecting that will be undertaken by the museum, spells out the criteria for selecting acceptable objects for its permanent collection and designates authority in selecting additions to the collection. It should also outline the procedures by which the policy is carried out. This policy is the capstone of the museum's documentation, and may be consulted in cases where museum collection procedures are in question. In

legal cases concerning museum objects the Collections Management Policy will serve as proof of a museum's standard practices.

Not all objects that enter a museum are destined to become part of the permanent collection. Unlike the early directive of the Tammany Museum, museums today do not, and should not, accept all objects that they are offered. Storage space and staff time are often limited and it is considered irresponsible to the rest of the collection to accept an object that will never be utilized. Objects that seem far outside the collecting scope of the museum may be rejected as legal donations by the Internal Revenue Service (IRS). For example, the donation of a violin to a museum that collects modern art may be called into question. The museum could be asked to show proof that a violin is an acceptable gift by submitting its Collections Management Policy to the courts. Therefore, careful consideration must be given in formulating the policy. It should be based upon the museum's mission, goals, and past history. It should not be so restrictive that normal collecting is hampered, yet it should not be so broad as to be meaningless. Its purpose is to identify the collecting priorities of the museum and to serve as a guide in the identification of potential purchases and appropriate gifts. The policy should incorporate existing areas of interest, as demonstrated by past collecting efforts, as well as desirable areas of expansion. It must take into consideration the organizational structure of the museum and all laws, guidelines, ethical standards, and appropriate practices. Common Collections Management Policy criteria include quality, relatedness, utility, control, and ethical considerations.

Quality is to be considered relative to the museum's existing collections. While it is ideal to acquire objects of impeccable excellence, the minimum standard for acquiring an object is that it be as good as or better than a similar object already in the collection. After reasonable determination of authenticity—verification of scholars, provenance, testing, etc.—the object will be graded according to esthetic merit and condition. Objects in poor condition should not be accepted unless the museum is reasonably sure funds exist for restoration or repair.

Relatedness is graded according to existing collections; it should fill a need or gap among existing holdings and enhance the overall collections. If it duplicates another object, will the collection be strengthened by having two or more similar objects?

Utility is defined by how well the object enhances the museum's goals and resources, and takes the following into consideration: exhibition potential, does the museum foresee exhibiting the object and with what frequency? Is the object's medium a limitation to its usefulness?

Control must be taken into consideration if there are any encumbrances accompanying an object that will have a negative impact on the museum's ability to manage the collection or are contradictory to ethical standards

embraced by the museum. Donors should be discouraged from placing any restrictions on their gift. Donor stipulations regarding retention and/or exhibition schedule may inhibit the museum's exhibition programming. No promises should be made about how often or how long an object will be exhibited. Often donors do not consider the negative impact of a lengthy exhibition time on their gift. They may not be familiar with environmental concerns such as over exposure from light and heat. Donor restrictions should not prevent the removal of the object through sale or trade from the collection. Any restriction that prevents the museum from its normal activities of exhibition and care should be avoided.

A statement should be included in a letter of acceptance from the director of the museum confirming that all objects must conform to the museum's ethical standards. These include ethical standards regarding collecting as established by the AAM, the Association of Art Museum Directors (AAMD) and United Nations Educational Scientific and Cultural Organizations (UNESCO). Museums will generally not accept human remains, objects that are suspected of being war loot or stolen during international conflicts, endangered species, or objects imported or obtained illegally.

Code of ethics policy

Museums in the United States are grounded in the tradition of preservation of cultural heritage. Nonprofit museums are organized as public trusts, holding their collections and information as a benefit for those they were established to serve. Members of their governing authority, employees, and volunteers are committed to the interests of these beneficiaries. The law provides the basic framework for museum operations. As nonprofit institutions, these museums comply with applicable local, state, and federal laws and international conventions, as well as with the specific legal standards governing trust responsibilities. Legal standards are a minimum. Museums and those responsible for them must do more than avoid legal liability; they must take affirmative steps to maintain their integrity so as to warrant public confidence. They must act not only legally but also ethically.^[3]

Codes of ethics exist for many staff positions within a museum, including Boards of Director, directors, curators, registrars, museum store managers, educators, and volunteers. Since 1999 the AAM has required every museum applying for accreditation to have their own specific Institutional Code of Ethics tailored to their collection and mission statement. They require that it be approved by the museum's governing authority. While not all museums apply for accreditation, most follow the AAM blueprint for the creation of an institutional ethical code, demonstrating to the public how seriously the museum takes its role as steward of the collections it holds in the public trust. Museums must be committed to public

accountability and be transparent as far as their day-to-day operations. Further, having a Code of Ethics cements responsibility to the collection in the minds of all staff. Guidelines and instructions for writing codes can be found on the AAM Web site, as well as in many reference materials. Topics include governance, responsibility to the collection, acquisition procedures, deaccession and disposal methods, public accountability and professional conduct, responsibility to the public, and conflict of interest for staff, volunteers, and members of the governing authority. Among these duties, one of the highest is to maintain truthful, complete, and accurate records of each object within the collection. This duty most often resides with the registrar and the information contained in the registration files.

Registration Files

Two types of files under the control of the registrar are: Documentary Files, those which contain accession and deaccession information about the individual objects in the museum's permanent collection, and Exhibition Files that relate to all exhibitions of the museum's collection as well as loaned objects from other institutions and/or individuals. Files containing research on individual objects, such as their historical or cultural significance, are generally gathered and maintained in the curatorial department, and are not included in the discussions here.

Accession numbers

Once the museum has confirmed that a new acquisition (addition to the collection whether by donation or purchase) is to take place the registrar should assign an accession, or inventory, number to the gift and its objects.

While each museum may choose its method of creating accession numbers, one traditional system uses a tripartite number that begins with the year of the gift, followed by a number designating its place among gifts given that calendar year by all donors, followed by a number designating each individual object's place within that gift. For example, if Mr. Smith donated three paintings, all given on a particular day in 2009, and it is the fifth gift the museum has received from all its donors that year, the number for the gift would be 2009.5. Numbers are assigned within that gift, to each individual object. Painting one will be designated as 2009.5.1, painting two will be 2009.5.2 and painting three will be 2009.5.3. In cases where the object may have several components, such as a tea set or a pair of shoes, a suffix may be added indicating that the objects are part of a larger set. In the example of a tea set, the gift may be 2009.7 while the tea pot is 2009.7a, a saucer may be 2009.7b, and a cup 2009.7c. Generally this system is used when all objects together form one exhibitable object. One saucer without the cup is not likely to be exhibited, nor one shoe without the other.

Documentary files

Every object belonging to the museum should have, at the least, some reference in a registration documentary file. Registration files document both the acquisition process and the care information for the objects in the museum's collection. They are distinct from curatorial files, often maintained outside the registration department. While curatorial matters are not the subject of this commentary, for the sake of clarity the difference is important to understand. Curatorial files contain research information on the individual objects as well as bibliographic references, exhibition histories, and other information of a curatorial nature that is pertinent to the display and use of the objects. Each file pertains to one object in the collection, and those may be arranged alphabetically by object name or type. Curators build these files as research is conducted and the objects are exhibited. Conceivably, not all objects will have a file if no information has been gathered or the object has not yet been displayed. Curatorial files may also exist on objects not in the collection of the museum, but which are similar in nature to those which the museum collects, for reference purposes.

Registration files, often called documentary or accession files, however, are created immediately upon the acquisition of new objects, perhaps even prior to the object's receipt by the museum. They record the acquisition event, whether by donation, purchase, transfer, bequests or other means, as well as subsequent care information. These files include incoming and outgoing receipts, deeds of gift, gift agreements or purchase information, loan agreements, condition reports, copyright licenses, letters of correspondence, packing and shipping documentation, object photographs, appraisals, and insurance records. Registration files in natural history museums may also include collection maps detailing the location of archeological digs, permits, licenses, and import/export documentation.

It is not necessary, or even desirable due to space limitations, to have an individual documentary file for each separate object because much of the content would be duplicated in each. Each file represents one gift, no matter how many objects are in that gift. If one donor, for example, gave the museum ten paintings at one time all of the documentation for the gift would be in one documentary file. The delivery information, the correspondence, the gift agreement and so on relates to one event. It would be redundant to have ten copies of each piece of documentation contained in ten separate files. Purchases, as opposed to gifts, are considered individual events, therefore each purchase is represented by one documentary file.

Creating the accessions file

Although retention schedules for many businesses recommend that files be purged after a certain number of years,

museum records should be retained forever. Provenance (ownership histories) field records, conservation treatments, and the like, cannot be traced without the retention of all records no matter how long ago they were created.

File with manila folders (or other similar types of folders) inside contain and separate the documents by subject. For long-term preservation of the original legal documents, such as the deeds of gift, they should be created using acid-free paper and stored separately in an acid-free folder. A fire-resistant filing cabinet kept in a secure location is an excellent repository for these documents. It is important to understand that any archival or acid-free file that contains documents on non-archival paper will, over time, lose its archival quality. The acids will migrate and contaminate any archival documents. Copies of these documents should be made for inclusion in the documentary file, while the archival master should be handled as little as possible.

Tabs on the exterior of the file folder contain the accession number of the gift, the name of the donor, and a brief description of the gift, for example, 2009.2.1-15, John Smith, 15 Masks. Files should be maintained in accession number order, which will also be a chronological order in which the accessions were made. File cabinets storing this or any other important documentation should not sit directly on the floor, but be raised at least three inches to protect against any water that may accumulate on the floor during a fire or flood emergency. Manila folders within the file will hold a variety of information depending on the museum's discipline. Common folder contents are: APPRAISAL, CONDITION REPORTS, CORRESPONDENCE, DEED OF GIFT, PURCHASE INFORMATION, INCOMING/OUTGOING RECEIPTS, LOANS, PHOTOGRAPHY, PUBLICATIONS, and NOTES. When marking the content of the manila file it is advisable to write directly on the folder's tab rather than applying a gummed label which will fall off the folder as it ages and dries out.

Each section of the file, described below, contains information regarding the legal status, the care and condition, and all other pertinent documentation relating to the objects in the collections. Proper maintenance of these files is one of the highest priorities of the registrar's job.

Appraisals

Donors preparing to make a gift to the museum often do so with the intent that they will take a charitable contribution tax exemption. In cases where the value of the contribution exceeds a certain dollar amount, the Internal Revenue Service requires that a certified appraisal be done on the object no longer than sixty days before the gift is made. Museum ethics prevent the staff from supplying a donor with an appraisal for a donation they expect to receive. Indeed, staff should remain at arm's length concerning any appraisal done for a potential donor. Should a donor

ask for a recommendation or help in finding a qualified appraiser, the museum should supply the donor with a list of area appraisers, preferably three or more names, none with significant ties to the museum. This is done to prevent even a suspicion that the donation hinges on a favorable appraisal in which the value of the object may be overstated. Similarly the museum should not pay for the appraisal nor any services provided by the appraiser including travel, meal, or hotel reimbursement. The IRS now requires that appraisals be done by certified appraisers who are recognized as such by a professional appraisal organization and to follow generally accepted appraisal standards. The law further calls for severe penalties for appraisers who intentionally under/over value property.^[4]

A museum may accommodate an appraiser's visit to the museum to view the object, should it be housed there prior to the donation. The museum staff may also assist the appraiser by providing photographs or other supporting documents, as long as the choice of the appraiser and the funds to pay him/her comes directly from the donor.

Because the appraisal is solicited and paid for by the donor, the museum should not assume that the documentation produced will be shared with the museum at the time of the donation. It is not unreasonable to ask the donor if the museum may have a copy of the appraisal in order to make sure that the insurance value placed on the object by the museum is accurate. Often donors will volunteer a copy of the appraisal, especially when they understand that it insures proper valuation for their gift. Copies of the appraisal are kept confidential, and should be kept in the object's documentary file.

At times the museum may choose to have one or more of its own objects examined and appraised for a variety of reasons usually related to insuring the collection or loan documentations. In cases where the museum already holds title to these objects, there is no conflict of interest and therefore no problems associated with the museum paying for the services of the appraiser. Care should be taken to only hire those appraisers who have been certified by a professional appraiser's organization. Valuations placed on objects by those without these credentials may be questioned or disallowed in the future.

Note that insurance values, often placed on loan agreements, are distinct from appraisals and may be assigned to museum objects by curators or others knowledgeable about the type of object. Insurance values may be higher than appraised values because they reflect not only the object's value, but also compensation for staff time in handling repair or replacement issues, should something be damaged.

Condition reports

Many publications offer detailed descriptions on how to write a condition report, and sample pages are provided

for recording damage to many types of medium. Therefore this section will only deal with general practices regarding condition reporting. Many different condition report formats exist, each one particular to the type of medium of the object. A museum is free to design its own condition report form but care should be taken to use terms common in standard museum practice and those appropriate for the object's medium.

A condition report is an account of an object's physical state at any given time. When an object first enters the museum, whether as a new acquisition or a loan, an examination should be conducted and the report written. Condition reports done at the time of acquisition establish a baseline of the object's physical status. Follow up examinations, done as part of an inventory or in preparation for an exhibition of the object, can be compared to the original report. If discrepancies are noted they may signal a problem with storage conditions that should be remedied. For example, buckling or wavy paper can indicate high humidity levels in storage areas; dry and cracked wooden items may signal that environmental conditions are too dry; these should be adjusted for proper object maintenance.

Condition reports done on objects coming to the museum on loan are done to confirm that both the borrower and lender are in agreement about the condition of the object and that no damage has occurred in transit. Loaned items should be examined immediately upon their unpacking at the borrowing institution. If there is a discrepancy between a condition report written by the lender and the report done by the borrowing registrar, the lender should be notified immediately. Objects with damage should not be displayed and may need to be returned to the lender for restoration or repair. Reports are completed again just prior to the object's return to its museum to insure it is being returned in the same condition as when it arrived. By careful examinations both before and after the exhibition, a museum may avoid accusations of responsibility for damage that did not occur on its premises.

Condition examinations are ideally conducted in a well-lit and clean environment. Common tools that assist with this process are: soft pencils, forms, rulers and or calipers, clean white gloves, flashlight, ultraviolet light, magnifying glass and/or jeweler's loupe, a rolling cart to transport objects and a metal measuring tape (a cloth or plastic tape will stretch over time and become inaccurate and should therefore not be used however care should be taken that a metal tape does not scratch the object).

Several methods exist to describe the location of damage on an object. Because condition reports are often consulted by someone other than the reporter it is vital that the location and the damage are described clearly and definitively. A zone method divides a canvas or other two-dimensional object into top, middle, and bottom sections as well as right, left, and center sections. Damage is noted,

for example, in the top left corner of the object, or bottom center, accurately conveying the location of concern. A second method of determining location is the axis method, in which damage may be described as located, for example, five inches to the left, and three inches up from the bottom. It is also acceptable to describe the location using the subject of the object. "There is a crack just above the man's eyebrow," can be just as clear as either of the previous methods described. The method used is not important as long as the information can be understood by any reader.

Damage is described in terms of length, width, color, shape, or another appropriate physical property. It is not necessary to determine the cause of the damage however, if known, that is helpful information. The extent of damage is referred to as negligible, slight, moderate, marked, and extreme.

Condition reports are to be stored in the object's documentary file and reviewed periodically. New information from subsequent examinations should be written on the original form and dated to indicate that it is not an original comment. Having all information on one sheet insures a much better historical report on the overall condition and is more efficient than locating and consulting several pages of old documentation.

Correspondence

Written correspondence between the museum and the donor can be important in determining the donor's intent to gift an object to the museum. In some cases heirs have disputed the validity of a gift made by a family member when that donor is no longer present to confirm their wishes. Correspondence between the museum and the donor often reveals clear intent to give the object to the museum. Courts will rule according to the donor's intent, often found within correspondence, despite the lack of a deed of gift or other receipt. This circumstance underscores the need for all file documentation, especially correspondence, to be permanently retained in the object's file.

Deeds of gift

Once the object offered for donation has been accepted by the museum the registrar will generate a deed of gift or similar conveyance spelling out the terms of acceptance. The deed should contain the name, address, and telephone number of both the donor and the museum, and a description of the object including as appropriate, title, artist, country of origin, medium, and dimensions. The donor states on the agreement that he has full ownership and authorization to make the gift, that he gives up all rights of ownership (with the possible exception of copyright) that the gift is unrestricted, and was not acquired by illegal means, and that the donor is not receiving any goods or

services in exchange for the gift. The museum should stipulate in writing that it accepts the gift. A letter of thanks from the museum usually suffices for written acceptance.

Two identical deeds are created on acid-free paper. The donor signs and returns both copies to the museum for signature by an authorized member of the staff. It is important, but not a legal requirement, for the museum representative to be the last signatory on the deed in order to prevent the donor from making unexpected additions to the agreement. Once the deeds have both been signed by the museum representative one fully-executed agreement is returned to the donor and the other is filed in an acid-free folder in a fire-resistant file cabinet dedicated only to archival materials. (Note: some file cabinets are referred to as “fireproof” a misnomer; at high temperatures of lengthy duration, metal cabinets can be destroyed by fire.) The deeds of gifts should be handled as little as possible in an effort to conserve them as long as possible. Copies of the deed are placed within the object’s documentary file.

While a deed of gift is a succinct document containing much of the information related to the donation, it is not a necessary component of the legal transfer from the donor to the museum. The law stipulates that for a valid transfer to take place there must be: 1) an offer; 2) an acceptance of the offer; and 3) physical transference of the object to the museum out of the control of the donor. Transfer may occur for example, when a donor writes a letter to the museum offering an object, the museum responds favorably to the offer and the donor delivers the object to the museum. A full and legal gift has not been made if any of these three components has not occurred. Therefore when a donor wishes to take a tax deduction in a particular year it is incumbent on the registrar to insure that the museum has actual physical control of the object by year’s end. Physical control means “under the museum’s care” and includes storage at a facility where the museum has contracted to store the object. As of yet, the IRS does not consider the gift complete if it is removed from the donor but still enroute to the museum.

Bequests

In some cases donors will request, through their wills, that some of their property be donated to a museum upon their death. These are considered gifts but there are special considerations involved. In essence, a bequest is an offer to a museum. The museum may or may not be aware of the plans of the donor; ideally the donor will have discussed their interest in making a gift after their passing, and the museum will have a chance to accept or decline the offer. In many cases the bequest comes as a surprise to the museum. Museums are under no obligation to accept post mortem offers, just as they are under no obligation to accept any other offer. In cases where the museum declines the offer the executor of the will makes other

arrangements for the object. If the bequest is accepted, the executor may sign the deed of gift and handles the transfer in place of the donor. Bequest documentation should be included in the documentary file, however it is not necessary for a copy of the will to be submitted to the museum as it may contain other, sensitive material. It may be permissible to photocopy just the pertinent section of the will for inclusion.

Purchase information

Not all acquisitions are made through donations. Museums often purchase objects for their collections, either from reputable dealers, auction houses, or private sales. In those cases there will be no deed of gift and a sales receipt will suffice as the conveyance of title. Details of the sales are still important and should be retained. If the purchase was done through an auction the catalog may be filed in the documentary file, along with any known provenance or dealer information that may be historically relevant.

Incoming and outgoing receipts

Receipts should be issued for any potential collection object coming into the museum or leaving it, even temporarily. Office furniture and equipment and personal objects are not treated in the same manner as collection objects and are excepted from this discussion. Objects may enter the museum to be reviewed as potential acquisitions at the request of the director or curator; as objects of scholarly study, loans, or, least desirably, as unsolicited objects left as a museum donations. A receipt should be issued that clearly states the owner’s name, address, telephone number, e-mail address, or other contact information. The receipt should state the purpose for which the object is left, and the expected date, if any, that the object will be returned to its owner. The object should be described fully enough to assist in identifying it, should that be necessary. Materials and dimensions are helpful, as is a short narrative recognizable by a lay person. Therefore a description of “a painting” will not suffice should the object become separated from its identifying information. More helpful would be “a framed painting, 16 × 20 in., oil on canvas, subject is a dog wearing a party hat.”

All receipts should bear the name and signature of the person receiving the object, as well as the person depositing the object. Terms under which the object will be held, such as responsibility for insuring the object, should be noted on the receipt. The addition of language describing the duty of the owner to keep the museum apprised of their contact information helps reduce the chance that loaned objects will be forgotten by the lender and become abandoned property in the museum. Although many states now have abandoned property laws specifically to aid museums in the acquisition or disposal of abandoned objects, the process is cumbersome and time consuming, particularly

if the object is not wanted by the museum. Registration staff should strive to return deposited objects promptly for the same reason. No object should remain in the museum without proper documentation.

A receipt should not substitute for a loan agreement; if the object is expected to remain in the custody of the museum for a significant length of time, or the museum has plans to use or exhibit the object, a loan agreement should be written that will spell out the responsibilities of both the lender and borrower, including insuring the object. See Loan Documentation below for further information.

Outgoing receipts are to be issued for any collection object leaving the museum, no matter how short the duration. The receipt should contain the same information as on the incoming receipt. If permanent collection objects leave the museum for conservation, photography, or similar purposes, a copy of the outgoing receipt should be given to the security staff who notes that the object is out of the building. The security staff should likewise be informed when the object returns to the museum. If an object is given back to its owner the receipt should state that the object is not expected to return. Under no circumstances should any object leave the building without a record of its removal. All receipts should be filed in the object's Shipping folder; they may be useful as records of the object's movement.

Loan records

Upon the return of an object that has been lent to another institution, a copy of the loan agreement should be placed in the object's documentary file with the original remaining in the loan file. Records of loans to other institutions are retained as part of the object's provenance. While this information may also be recorded on the museum's collection database, it is important to have the original loan agreement that contains all the information pertaining to the loan. Having the agreement at hand may assist with future grant applications that request the museum's loan history.

Standards of care include the responsibility to limit the number of hours sensitive objects are exposed to light. Light exposure records for individual objects should include times when the object has been on loan, just as they would for objects on exhibition in their home museum. Having a copy of the loan agreement can assist in the calculation of these hours. Incoming and outgoing loans are discussed in a later section. Further information concerning loans is discussed in a later section.

Photography

Documentary photography is an important part of any object's file. When an object first enters the collection a photograph, even one of low quality, is immediately

taken, marked with the object's accession number, and stored in the Photography section of the file. Documentary photographs are to be used only for object identification; their quality is not adequate for publication.

In ideal circumstances all objects would have a series of publication-quality photographs taken as soon as they enter the collection as a part of the accession procedure. Unfortunately staff availability and financial resources often preclude this from occurring right away. If and when a publication-quality photograph does become available it can be stored in this file. If it is stored in another location, such as in a curator's or publicity manager's office, its existence should be noted in the documentary file. Additionally, surrogates of the image should be linked to the object's record in the collection database and in the museum's digital asset management system as appropriate. Publication-quality photography may also be held by the donor, gallery, or auction house from which the object came. These sources are often willing to provide the photos to the museum.

Copyright considerations should be observed when planning to publish any photograph of museum objects. While "fair use" or "educational use" may be defenses, it should not be assumed that any museum use of photographs is allowed. In addition to artist rights, the photographer often holds copyright protection. It is a wise decision to note any copyright information in the object's database.

Registration staff often assume the task of photographing one or more objects in the permanent collection for documentation purposes. For efficiency, a time is set aside when photography of a number of objects can occur at once. Objects to be photographed are grouped according to size to avoid frequent camera adjustments. Very small objects may benefit from having a ruler, a coin, or other measuring device placed in the photo in order to help the viewer determine the object's size accurately.

A neutral background is selected so that visual distractions do not interfere with the photograph. Depending on the size of the object a neutral background can be created by placing a piece of foam board or cloth behind the object. Wide rolls of photography paper (purchased from local photography stores) may be hung on the wall behind larger objects.

Photo flood lights are placed on both sides of the object at approximately the same height as the camera and about six to eight feet from the object. Cool burning lights specifically for studio photography are used. Nonetheless, use of any light is judicious as all light exposure can damage most objects by varying degrees. Lights are not placed in close proximity to objects, nor are they left burning when the object is not actively being shot.

Each object is photographed by itself to avoid any confusion or background interference. Lighting must be adequate and care is taken that shadows do not fall across the object. Should there be important markings on the

object, more than one photograph may be necessary. Markings on the bottom or reverse of the object are also included. The object's accession number may be legibly written on an index card or similar paper tag, and displayed prominently in the photograph without interfering with the subject. This aids in identification of the object absent any writing on the photograph.

The viewfinder area is filled with the object and the focus is as sharp as possible. While some photographic errors can be reduced or corrected with digital manipulation it is better to take a good quality shot the first time.

When possible framed works are unframed prior to being photographed otherwise glare can hamper the quality of the final product. If unframing is not possible the use of polarizing screens and/or filters helps to reduce any reflection. If glare persists lighting should be moved until the glare is reduced or eliminated. When photographing a flat object from above, the camera must be secured by a tripod or strap around the neck of the photographer so that it does not fall onto the object. Use a secure tripod or keep the camera's strap around your neck at all times.

Publications

From time to time the objects in a museum's collection may appear in publications. Whether they are scholarly texts, museum catalogs, newspaper articles, museum receptions, or another form of printed media, copies of the publication are retained, and stored in the object's documentary file. If the publication is a book or other cumbersome format, a reference to the publication and note about where the book is stored in the museum should be placed in the file. Similarly, if the reference is an Internet site a note in the file listing the URL and the date it was first posted is acceptable. Because of the transient nature of the Internet, it is best to print a hard copy of the Web page showing the object and its reference. This does not apply to aggregate Web sites where large groups of objects are published, such as ArtStor or the California Digital Library, for example.

Notes

The notes section of the documentary file is meant to hold all notes, memos, and internal correspondence concerning the object. Memos written to alert staff that an object is entering or leaving the building, requests for preparation work or installation schedules should all be retained and filed in chronological order. Leaving these types of notes intact and available in the file will assist future staff who research an object's movements.

Other sections

Depending on the museum's discipline and governance there may be other types of information that is gathered

and preserved in the documentary file. Natural history museums may have sections for field notes, maps, excavations, among other things; zoos and aquariums may have information on their "living collections' fish and animals" historic homes may have files relating to furniture restoration, and so on. No matter the discipline an accurate history of the museum, its collections, and the objects themselves can only be assured if the information is clearly documented and carefully preserved. The staff must keep in mind that electronic storage devices such as computers and their software programs will become outdated and the information held by them may not be accessible if it has not been kept up-to-date.

Deaccessions

Museums generally accept objects into their collections through the process of accessioning, an act of recording and processing the object and its documentation. Acceptance of any object into a museum's collection is a thoughtful process taking into consideration the benefit the museum and its visitors will enjoy, the ability of the museum to care for the object, its suitability for exhibition, its appropriateness for the collecting mission of the museum, its quality, its freedom from excessive donor restrictions, as well as all laws, guidelines, and ethical considerations. The decision often involves the staff, collection committees, boards of directors, as well as the donors. Laws regulating museums and their collections are promulgated by state and federal laws including those involving the Internal Revenue Service. Every attempt is made to accession wisely. Objects in museums validate our culture and the heritage of peoples around the world. Museum personnel take this fiduciary responsibility very seriously, realizing that public trust is sacred. Donors give objects to the museum with the expectation that the objects will be kept, cared for, and preserved for future generations to come. Museums are loathe to act in a manner that would imply that this trust is misplaced. Making a decision to permanently remove an object from the collection for any reason is therefore done in a thoughtful and well-considered manner. Museums exist to serve its public and to do so they must have the confidence of their community. Deaccessioning is related to the museum's purposes, policies, resources (staff, physical facilities, acquisition, and conservation funds), and long-term goals and is not intended to be a reflection of the particular tastes of the period or individuals involved. A decision to deaccession objects in the permanent collection should be considered not only in light of the law, but with regard to the museum's public trust.

From time to time it may be necessary to remove objects from the collection in the interest of constantly improving the collections and maintaining a high standard of esthetic quality and historical importance. Museums must retain the right to deaccession any item, however

acquired, which does not meet standards which demonstrably enhance existing collections, esthetically fulfill an identifiable instructional purpose, or contribute in significant ways to an academic or research program. Deaccessioning and disposal of museum objects must be conducted in accordance with museum policy and any applicable state and federal laws. Criteria applied to deaccessioning and disposal are as stringent as those applied to the museum's acquisition process, and reflect professional standards of ethics as established by the Association of Art Museum Directors and the American Association of museums.

Regulations cover the circumstances under which an object may be deaccessioned, as well as what may be done with any funds or other proceeds realized by this process. These regulations apply to a wide variety of museum disciplines whose objects may break, wear out, or degrade to such a state as to render them useless for the museum's purposes. Living history museums often use their objects in educational demonstrations which contribute to their deterioration. Zoological collections include living mammals and fish whose remains must be removed from the museum collection at death.

Authority to deaccession

The authority to determine the disposal method lies with the museum director and the board of directors. Criteria, authority, and procedures for deaccessioning should be contained in the museum's Collections Management Policy. Legal consultation will help insure that all existing laws and regulations are satisfied by the procedures adopted by the museum and incorporated in its policy. Depending on the size and discipline of the museum, and the value of the object in question that authority may shift. In a natural history museum, where scientific specimens that have little or no market or scientific value are added and removed from the collection as a matter of course, the decision may rest with the curator or others working with the collection. In a publicly funded art museum where the object is of significant value, or a majority of the museum's collection is being considered for deaccession, the state's attorney general may be consulted to ensure that the terms of the sale are fair and reasonable and that the purpose of the organization is promoted by these actions. The greater the object's value the higher the decision-making authority must be.^[5] A general guideline is that the level of authority to remove an object should be equal to or higher than the level of accessioning it.

Criteria for deaccessioning

Objects meeting certain criteria are deemed acceptable to deaccession. Such criteria include the following: the museum's inability to preserve or care properly for the object; the extent to which an object may, in the context

of the collections, be redundant or a duplicate of equal or inferior quality; an infestation or other condition of an object which cannot be ameliorated that makes it dangerous to other objects in the collections; the object's lack of relationship to the museum's collections; objects below museum quality standards, either intrinsically or relatively, in comparison with objects of the same type in the collections; the existence of an object in the collections in violation of UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property; objects determined to have been missing over five years; specimens that are deceased, or the discovery that an object has been misattributed, falsely documented, and/or is considered to be a forgery (in which case the museum's records must be changed to reflect the object's rightful attribution). In some cases objects may still be useful for study purposes and can be retained; deaccessioning does not demand that an object be removed from the museum.

Verification of records

The museum must confirm clear and unrestricted title to any object being considered for deaccession. The records of donation, if any, must be consulted to ascertain that no contractual contingencies in a gift prevent a deaccession. Legal counsel may need to review the validity of any restrictions that have been placed on collection objects that may interfere with the deaccession process. No collection object that has been acquired by gift or bequest with a restriction as to its retention should be deaccessioned while said restriction remains in effect, unless the retention of the object presents a clear, physical danger to other objects in the collections or unless it is proven that the object is held in violation of the UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property.

Precatory (nonbinding) stipulations which do not impose any accompanying legal obligation are respected to the extent possible, unless modified by the donor, or if the donor is not living, the donor's heirs or legal representatives. If the object is unrestricted the museum may proceed with the deaccession. Unless stipulated in the accession documents, donor notification of deaccession procedures is not necessary. An object given to a museum without restriction becomes the museum's property to be administered as the museum sees fit. Some museums adopt a good-will policy under which the donor or surviving family may be notified of a deaccession but this is done only as a volunteer practice.

The deaccession procedure

All deaccession action must be approved by the governing authority. In areas where, in the opinion of the

director or board of directors, museum staff expertise is not adequate to determine suitability for deaccessioning on the basis of authenticity or quality, outside professional advice is secured. Expert opinions may be sought from outside consultants who are acknowledged specialists in the field.

Once it has been determined that no detriment to the deaccession exists, the museum generates a written justification for the deaccession of the object in accordance with the criteria for deaccession described above. This justification generally includes an estimate of the object's current value, a recommendation for the method of disposal, and the date acquired; value at time of acquisition (if known); the source of acquisition, and stipulations, if any, detailing terms of the gift or bequest, and, if appropriate, an estimate of the amount of money that can be expected from this act. This justification and any report of the proceedings is included in the object's documentary file.

Disposal of deaccessioned objects

Deaccessioned objects may be transferred or donated to other museums or agencies as appropriate, they may be sold, donated, exchanged, or if necessary, may be destroyed.

Any sales should be conducted openly, preferably at auction. An object may be offered for donation or exchange to another museum or suitable institution for the express purpose of keeping that object available to the public. As mentioned above, in some circumstances the museum may elect to retain the object but reduce its status and subsequent level of care, to be used for educational purposes. Of course this would not be a factor where it was determined that the object had been stolen or otherwise illegally obtained, and in the case where the object was a living specimen, if it had died.

Ethical considerations in art museums demand that no employee, representative, or agent of the museum may receive any benefit, including the right to purchase any work of art removed from the collection. A conflict of interest may arise if employees may both suggest that a work of art be removed from the collection and purchase or otherwise receive that work of art once it has been removed.

As stipulated by the AAM and endorsed by the American Association of Art Museum Directors, all proceeds from the sale of works of art may be used only to acquire other works of art for the collection or to fund conservation of its collection. Ideally the museum will use the funds to purchase a similar yet superior work of art to that being removed. This considers the wishes of the donors who gave the original object to the museum. By selecting a similar work of art the

intentions of the donor are presumed to attach to the newly purchased work of art. Works acquired with the proceeds of sales of donated items should, if feasible, be credited as an original gift from the donor of the work that was sold.

A recent debate in the nonprofit museum community has arisen that surrounds proceeds from the sales of collections objects that fund building projects, facilities maintenance, or other institutional operations. The 1992 code of ethics for the American Association of State and Local History offers the following guidance concerning proceeds: Collections shall not be deaccessioned or disposed off in order to provide financial support for institutional operations, facilities maintenance, or any reason other than the preservation or acquisition of collections.^[6] In 1994 the AAM promulgated a revised code of ethics which contained a similar statement:

Disposal of collections through sale, trade or research activities is solely for the advancement of the museum's mission. Proceeds from the sale of nonliving collections are to be used consistent with the established standards of the museum's discipline, but in no event shall they be used for anything other than acquisition or direct care of the collections.^[7]

The definition of direct care has been left to the individual museum.

While the law has been more receptive to a broad interpretation of use of deaccession procedures, common ethical practices support the more strict understanding. A museum's mission invariably centers on the maintenance and use of its collections. When the collections are treated as assets they cannot serve the public trust. Museums facing serious financial difficulties argue that without this source of income they will shut down completely and will not be available to serve the public at all. This debate underscores the reality that laws can be enforced whereas ethical codes uphold the integrity of the profession and may be more demanding than the law.

Records of deaccession procedures

Complete and accurate records, including photographs and documentation of the circumstances of its disposal, are maintained on each object removed from the collections. At a minimum the records should include copies of the original accession documents, the museum's written justification for deaccession, any records of expert opinion, the record of disposal method and use of proceeds, and a photograph of the object. These records are kept in perpetuity but not stored with the documentary files of the current collections. The registrar adjusts the records to reflect the deaccession action.

Loan Documentation

Duty to loan

In July of 2000 the AAM wrote guidelines on exhibiting borrowed objects. An excerpt from the guidelines says this:

Over time human societies have increasingly turned to their museum to provide a special place, a *sacred precinct*, for the display of significant objects and ideas created by human civilization. Since no museum contains or could contain, all objects worthy of admiration and understanding, museums have traditionally exhibited not only objects from their own collections but also objects from other museums and private individuals and organizations. Borrowing objects allows museums to provide more comprehensive exhibits and to make objects accessible that would otherwise be seen only by a few.^[8]

Most museums have within their Collections Management Policy criteria and procedures to both make and receive loans. As educational institutions museums welcome the opportunity to exhibit objects from other areas, and to use those objects to enhance and highlight their own collections. Loan agreement forms are usually generated by the registration department and the documentation that ensues is permanently housed in that department. Like other museum documents, these records are kept in perpetuity.

The registrar's role in loan discussions centers on the objects that will be loaned. The registrar, as manager of the collection, keeps the schedule of the objects that have been selected for its own upcoming exhibitions, as well as those that are scheduled to travel to other institutions. The registrar also oversees conservation schedules and maintains environmental exposure records that indicate the maximum amount of time an object can be responsibly displayed. Decisions to loan or accept a loan are usually made by the director and curator, keeping in mind those important considerations. A registrar's records must be kept up-to-date and accurate in order to contribute to a wise decision.

Loan requests

When an object is requested for loan by another museum the registrar may request that the borrowing museum complete a Facilities Report, a standard but lengthy report that details the building construction, the environmental controls, exhibition and storage areas, the expertise of the staff and the handling, and collection practices followed by the borrower. Careful review of this document may reveal concerns surrounding the loan. Any issue the lender has with the borrowing museum or staff should be addressed and cleared up before the loan process proceeds.

In addition to the institutional practices of the borrowing museum, the lender should be concerned with the reason for the loan request and the circumstances for the

exhibit. It is standard practice not to lend objects to individuals. Museums collections are maintained for the benefit of the public and it is hard to justify their exclusive use for any one individual. When museum objects are on loan they should be afforded the same standard of care and protection as when they are in their own museum environment. Private homes or offices cannot replicate the security nor the controlled atmosphere that a museum can. Additionally, tax regulations require donors to relinquish complete control over the items for which they have received a charitable contribution exemption. If donated property was lent back to the donor, even temporarily, the deduction could be called into question. Staff members of the museum, including the board and volunteers, have a duty not to receive any personal benefit from their positions. Lending museum objects to a staff member is a direct and serious violation of this ethical consideration.

Some institutions have a policy of only lending to a certain type or size of museum. Some may lend only to educational museums, some to museums within their state, some only to institutions their size or larger. Many larger museums will not consider loaning an object to another institution that has not been accredited.

Loan agreements

Once a loan has been accepted by the lending museum the registrar crafts a loan agreement with responsibilities of both lender and borrower clearly designated. Loan agreements may be written by either the borrower or lender. In some cases both institutions write an agreement to insure their particular concerns are met. In this case the registrar should carefully review each document to make sure they do not conflict with each other, nor with state regulations.

Components of the agreement include: a description of the object being lent, dates both of the arrival and return of the object and dates of the public exhibition, name of exhibition, instructions on what to do if an object is damaged, caution against cleaning or altering any work in any way, including reframing; the expected standard of care for the object, the necessity of condition reporting, who may pack and transport the object, who may handle the object at the borrowing museum, cost assignments for transportation, conservation, framing, and insurance, information on how to unpack and repack, and who insures the work in transit and on site. The lender may ask for a diagram of the gallery and layout of the show in order to check the anticipated traffic patterns. A covered vitrine, a raised pedestal, or stanchions may be requested to protect fragile objects in high density areas. Other issues that may be contained in the agreement concern who may get invited to the opening reception, courier or travel costs to be reimbursed, and any sales costs for museum catalogs or other exhibitions support materials.

Once the registrar has completed a written agreement with all the supporting information, two originals are sent and signed, each museum keeping one of the originals. Copies of the agreement may go to the director, the curator, and the business office. The original loan agreement should be kept on file in perpetuity and copies made from which to work.

Creating the loan file

The loan file is the repository of every scrap of information pertaining to the loan, from the first loan request to the object's return. A loan number may be assigned in a similar manner as are accession numbers. A commonly used system uses an alpha-numeric designation such as Outgoing Loan (OL) or Incoming Loan (IL) followed by the year in which the loan will begin plus the number of loans that have been created for that year. For example, the third outgoing loan in 2009 would bear the number OL2009.3. Depending on the database, if any, different configurations of the prefixes may be used to help sort the loan information.

Tabs attached on the exterior of the file folder contain the loan number, the exhibition dates, and the institutional name of the lender/borrower. Files are maintained in a chronological order. File cabinets should not sit directly on the floor, but be raised at least three inches to protect against any water that may accumulate on the floor during a fire or flood emergency.

Manila folders within the file will hold a variety of information depending on the museum's discipline. Common incoming loan folder contents are CONDITION REPORTS/PHOTOGRAPHY, CORRESPONDENCE, INSURANCE, LOAN AGREEMENT, NOTES, PUBLICATIONS, and SHIPPING. Outgoing loan folders may contain the same designations with the addition of FACILITY REPORT. When marking the content of the manila file it is advisable to write on the folder's tab rather than applying a gummed label which may fall off the folder as it ages and dries out.

An additional folder within in the exhibition files should be designated LOANS DENIED. Historical information on loans which have been requested from the museum but for whatever reason did not occur. Correspondence between the borrower and lender concerning the denied loan are kept here.

Condition reports: Incoming

Condition reports insure that both the borrower and lender are in full agreement on the condition of the loaned objects. While a condition report done as a matter of standard operations for collection objects aids in long-term tracking of condition, a condition report done in a loan situation protects each institution from unfounded

claims of damage. Incoming loan objects should arrive at the borrowing museum with an individual condition report for each object. If there are no reports the receiving registrar should prepare them and immediately send copies to the lending museum. While it is an imposition of time and effort, the protection afforded the borrowing museum is priceless. Numerous manuals exist to aid in completing condition reports on a wide variety of materials. Consulting an appropriate form will aid the speed with which one can complete this process.

Condition reporting is best managed by a two-person team. One person reads the existing report (or writes one, if no report exists) while the other examines the object to confirm the report. Should damage to the object be discovered that is not on the report, the lending registrar should be notified. Judgment should be used to determine if the damage is slight and was just overlooked, in which case the registrar may add the observations to the report, sign and date them, or is new damage that has occurred in packing or transit. If damage to an incoming crate or container is obvious the damage should immediately be reported to the shipper, as well as to the lending registrar, preferably while the drivers are still on premises. The packing material in a damaged container should not be discarded; it may hold shards or other material necessary for the repair of the object. It can also indicate how the damaged happened, which may impact the person financially responsible for the damage.

The loan agreement contains instructions on what to do when damage is found. Under no circumstances should the borrowing museum staff attempt to unframe, clean, repair, or alter the object in any way without written permission of the lender. A telephone conversation to the lender should be followed by a fax or e-mail detailing the damage in writing along with photographs of the damage. The lender should reply, in writing, giving instructions on how to proceed. If the lender is not familiar with museum procedure (in the case of a private lender, for example) the options can be outlined to the lender so they may grant written permission, in writing, to have the repair made.

If after the object has been examined and its condition is as stated in the report, the examiner should so indicate by writing "No Change" on the report, sign and date it. It is not necessary to reiterate any damage that is already listed on the report.

When the loan period comes to an end, a second round of condition reports is completed for each object. On the original report it may again be noted "No Change" if the object is in the same condition as when the first review was done, along with the examiner's signature and date. If damage has occurred while on the borrower's premises it should be reported immediately to the lender following any instructions in the loan agreement and noting the damage on the condition report. It is helpful to include any photographs of the damaged area with the report.

Condition report: Outgoing

When sending an object to another museum, the object is carefully examined for condition. Numerous manuals exist to aid in completing condition reports on a wide variety of materials. Consulting an appropriate form will aid the speed with which the process can be completed. A photograph or rough sketch on which indicators pointing to each area of damage has been drawn, makes the report easier to understand. Any observations should be clearly written so that anyone reading the report will understand what is being conveyed. As with all condition reporting, it is easiest to accomplish using a two-person team. One person will examine the object and report verbally, while the other makes accurate notes on the report.

Should the loan be to multiple venues, and/or there are many objects in the loan, a condition report notebook should be compiled in a three-ring binder and sent along with the objects. In addition to condition reports and accompanying photographs the notebook may include any special packing or exhibiting instructions, a crate list indicating which objects are contained in each crate, and contact information for the registrar, curator, and publicity person. Packing instructions may be on paper and in an electronic format. A video of packing or assembling complicated objects can be invaluable.

Correspondence

Prior to a loan being realized there will be correspondence, generally between the borrowing and lending curators, that will contain information such as details of the exhibition, the reason for the exhibition, why certain objects are being requested, other lenders to the exhibition, and stipulations concerning the loan. All of this information is important and may answer future questions or assist in settling any disputes. These notes should be retained in the correspondence folder.

Insurance

Proof of insurance for either party should be retained in this file. Often the borrowing institution will issue a Certificate of Insurance that confirms that the borrowed objects are covered by the borrowing museum's policy. Either the borrower or the lender may choose to insure the objects. This information should be contained within the loan agreement.

Loan agreement

The original signed loan agreement should be preserved in this folder. Because it is a legal document it should remain as pristine as possible. Copies may be made and circulated to those staff members directly involved with the loan

(including the development officer), however the original should remain in the file.

Notes

This section of the loan file should store any internal notes between staff referring to any meetings, schedules, requests for labor, or any similar material.

Publications

Any catalog created for an exhibition which contains references to the museum's objects should be kept as a record of the exhibition. Any exhibition opening invitations, copies of newspaper or magazine articles should also be retained. Pertinent online articles should be printed out and filed with the URL and the date accessed noted.

Shipping

Any shipping invoices, correspondence to shipping companies, bills of lading, or any documentation concerning the movement of objects pertaining to the exhibition should be stored here.

PROTECTION OF RECORDS

In addition to maintaining the information the registrar assumes responsibility for the physical safety of the files. Long-term retention is the goal; ideally the information will be readily available for the life of the museum, no matter how long that may be. Acid-free materials and folders should be used for all legal documents and records that are deemed archival. Acid-free pages should not be stored with acidic pages nor stored in acidic file folders as the acid will migrate and contaminate the acid-free materials. All pages should be free of paper clips, staples, and creases, factors that degrade paper. File labels should be written directly on the folder, not attached by a sticker that will fall off once the glue ages. The file cabinets should be stored in an environment conducive to long-term preservation. High heat and humidity conditions should be avoided. Because much of the material contained within the files may be sensitive, the files should not be accessible to the public, nor to any staff not directly involved with collections care. Storage in a locked cabinet is preferred. Staff should be reminded that the information contained in the files is confidential and should not be shared with others.

The material in the documentary files may be duplicated in part in a museum's computerized data management system. Backup procedures should be done on a regularly scheduled basis to insure that the material is up-to-date, accurate, and safely maintained. Backup records should not be stored in the same building as the computer.

A secure offsite location, known by more than one person is recommended for all backed up computer records. Unless they are on a network server that automatically stores and backs up documentation. Because data management systems constantly evolve, they are not part of the further discussion of records management.

All records must remain secure from hazards such as fire, theft, and water damage. Slower acting agents of destruction also present a hazard to the collection such as light exposure, pests, acid reactions to paper, and mishandling. Safeguards should include restricting food, drink, and smoking from record areas, nearby fire extinguishers (and the training to use them), and a system for locking and monitoring access. Managing collections is a rigorous task. Even museums with few resources can design systems to safeguard both the collections and its pertinent records.

CONCLUSION

A museum's documentary records on its objects are unique and irreplaceable assets of the organization and should be systematically collected and preserved. These records allow personnel to properly care for and access the museum's collections. Records prove ownership, describe the material in the collection, and document loans. They insure that museum collections are physically and intellectually available for collections management, interpretation, exhibition, and research. They demonstrate accountability for the collections. Today, as the public

demands more accountability from those who steward objects of cultural heritage, it is more important than ever to preserve this important documentation. Governing authorities such as the AAM regulate what information a responsible museum should preserve.

Documentary records can be considered secure as long as information is entered in a timely manner, access is restricted to those working directly with the records, errors are corrected as soon as they are discovered, and the museum's standards of practice address the importance of these files and their contents.

Museum Studies

Marjorie Schwarzer

Museum Studies Department, John F. Kennedy University, Berkeley, California, U.S.A.

Abstract

Defined at its most basic level, “museum studies” sometimes referred to as “museology” or “museum science” is the study of museums. Since its origins in the early 1900s, its development has been tied to ongoing discussions within associations like the American Association of Museums (AAM) and the International Council on Museums (ICOM) about how best to train those who work in professional roles in museums. Beyond its emphasis on practical training, museum studies scholarship also explores museums’ cultural, political, and historical roles within society. Universities and other research institutions, like the Smithsonian and the Getty, offer a range of museum studies courses, graduate degrees, workshops, research, and publications. There is debate about how to approach the study of museums. The entry below offers discussion on these issues from a historical perspective. It largely focuses on the United States, although it should be noted that museum studies programs and scholarship exist around the world. Given the complexity of the museum field and museum studies and the number of individuals who have made contributions to its advancement, the discussion below is by no means exhaustive or complete.

INTRODUCTION

Defined at its most basic level, “museum studies” sometimes referred to as “museology” or “museum science” is the study of museums. This study, according to the Smithsonian Institution Center for Education and Museum Studies, encompasses “the ideas and issues involved in the museum profession—from the practical, day-to-day skills needed to operate a museum to theories on the societal role of museums.”^[1] Museum studies is interdisciplinary and is thus undertaken by individuals from a variety of backgrounds and disciplines, including, but not limited to: 1) university professors and other scholars who incorporate museums as part of their research or apply their academic discipline (e.g., Anthropology) to an understanding of various aspects of museums, 2) university faculty who teach courses to students who are pursuing academic degrees in museum studies, 3) adjunct instructors who are employed by museums or are retired professionals and teach one or two university courses on topics like museum collections management or museum ethics, 4) practitioners in museums or in independent research institutions who research and publish studies about different trends in museum practice (e.g., visitor studies), and 5) individuals who hold academic degrees and/or certificates in museum studies.

Museum studies departments are housed at a select number of universities throughout the United States and around the world, either as sections of traditional academic departments, such as a Department of Anthropology or Art History, or as stand-alone departments in Schools of Education, Liberal Arts, Library Sciences, or

Continuing Education. Other museum studies departments are run by educational and research divisions of large institutions, such as the Smithsonian Institution. Typically museum studies departments offer services like workshops, conferences, publications, and reports related to museum work, research and credit courses that lead to a certificate or master’s degree in museum studies. These courses cover topics such as museum history and theory; administration; marketing; collections management; education; technology; exhibition design, ethics and law; and community outreach.

A variety of organizations, ranging from professional museum associations to academic presses, publish journals and books that disseminate museum studies research. Some publications are theoretical in nature and address different philosophies on the role and meaning of the museum in society. Others take on more practical aspects of museum work such as how to design exhibitions and public programs, preserve a specific kind of fragile artifact, understand museum audiences, or measure economic viability. Still others meld theory and practice. In addition to academic journals and books, museum studies research is disseminated through trade publications and professional committee newsletters.

Despite the growing number of museum studies publications, researchers, college-level courses, and universities that offer a master’s degree or certificate in museum studies, there is little agreement or cohesiveness within the field. Since the institution of the museum encompasses a staggering array of organizations, collections, disciplines, organizational structures, public services, economic models and professional practices, it follows that the field of

museum studies is equally disparate. Many professionals who work in museums are not acquainted with or knowledgeable of the field of museum studies. Likewise, many museum studies scholars, researchers, and professors have limited direct work experience in museums.

Given the varied perspectives, there are lively debates about the nature, stature, and future of museum studies. These debates address issues such as: 1) standardization of curriculum and accreditation of university and other museum studies training programs; 2) the knowledge, skills, and learning outcomes that museum studies curriculum should strive for; 3) appropriate subfields of study, such as visitor studies, curatorial studies, ethics, legal issues and educational learning theory; and, of course, 4) the ever-changing nature of museums themselves. Museum studies scholars have been instrumental in framing key intellectual issues in the field including the repatriation of looted objects, the role of indigenous peoples in creating museum displays of their culture, how the design of galleries shapes the visitor's experience, and the tensions between creating entertaining blockbuster shows and more scholarly interpretations of collections.

EARLY HISTORY OF MUSEUM STUDIES

The history of museum studies is tied to the development of museums as professional workplaces, and the ongoing need for trained employees. It should be noted that although most museum practitioners and academicians agree that a museum is a professional workplace, some do not believe that museum work is a distinct profession, another contention in the debates about museum studies.^[2]

Stemming from their beginnings as royal and priestly cabinets of curiosities and then private collections in Europe during the fifteenth and sixteenth centuries, early museums were eclectic, described by museum historian Edward Alexander as “individualistic and unorthodox,” and subject to decisions by wealthy collectors and benefactors that were “uncertain, haphazard, and wasteful.”^[3] Even as museums became more accessible and thus more accountable to the public during the seventeenth and eighteenth centuries in France and England, and likewise in the nineteenth century in the United States, no attention was given to developing a coherent set of practices, or focused study of, the growing phenomenon of gathering art and natural science collections, studying, and classifying them, arranging them in publicly accessible displays, and managing their care and upkeep.

As museums grew in number, especially in major cities in the United States after the Civil War, great attention was paid to amassing collections and developing an architecture to house them that communicated grandeur. But no internal system existed for training employees to manage or care for them. Most museums were run by their founders, their founders' relatives, or other volunteers who had

personal financial cushions and could forgo a salary. A high number listed their occupation as “amateur archaeologist” or “volunteer.” Some doubled as benefactors, donating their own collections and inheritances to keep their museum afloat. In short, museums remained the purview of wealthy hobbyists.

In 1891, G. Browne Goode, a curator at the Smithsonian Institution, wrote the first American book to lay out ideas for the professional management and organization of museums. In *The Museums of the Future*, he opined that not just anyone could run a museum. Museums needed employees who possessed a “museum sense” meaning that they understood the unique qualities of collections, exhibitions, and public display.^[4]

A collective “museum sense” was slow in coming. Professionals working in other types of scholarly and public organizations had begun to develop a collective sense of profession in the nineteenth century. Several autonomous professional associations—for example, the American Bar Association (1878), the American Historical Association (1880), and the American Library Association (1881)—were born at that time. In 1889, the first association of museum workers—the Great Britain Museums Association—was founded in York, England. It held meetings where various ideas and practices were discussed. In 1902, British museum workers published the field's first professional journal: *Museum Journal*. Those working on the other side of the Atlantic Ocean were intrigued. The Salt Lake City Museum of Utah was the first foreign museum to join the Great Britain Museums Association, and Americans began to sail to England to participate in meetings.

In 1905 at the Smithsonian Institution a group of museum workers who had been attending the meetings in England set forth a charter for an independent American museum association. The next year, in New York City, at the American Museum of Natural History, 71 individuals working in art, natural science, and history museums held the foundational conference of the American Association of Museums (AAM). Within a year, they had recruited 160 founding members (mostly curators). Their idea was straightforward. Museums, whether devoted to art, science, history, or a combination of all three, had common interests and goals. Therefore, people working within them would benefit from a formal network through which to share practices. As the Smithsonian reported: “the importance of this movement so auspiciously inaugurated cannot be overestimated, since the opportunity for interchange of views will surely stimulate the activities of museums everywhere. . .”^[5]

American Association of Museums became a forum for workers (they called themselves “workers” through the 1940s, then used the term “museum people,” and finally, around the late 1950s, the then-disputed term “professional”) to develop their own voice, while remaining obedient to their places of work, and their patrons.^[6] Scarcely

anyone knew how to organize exhibits, deal with artifacts, or run museums. Scarcely any literature existed that described what a museum was and what it should do. In 1907, Frederic A. Lucas, curator of the Museums of the Brooklyn Institute of Arts and Sciences, wrote about the shortage of information and workers in an expanding field. Where could he find trained taxidermists, landscape artists, and preparators to help create exhibitions?^[7] That same year, *The Nation* ran an editorial noting that despite the shortage of workers, wealthy philanthropists continued to found new museums. What was needed, the editorial suggested, was a specialized curriculum devoted to training a cadre of curators to advance the work of museums. This curriculum should include a thorough understanding of classical antiquities, as well as an understanding of how European museums operate. Around the same time, A. R. Crook, curator of the Illinois State Museum of Natural History, surveyed AAM members and synthesized their ideal qualifications needed to run a museum. His recommendations were: “a knowledge of museum history and philosophy; a grasp of exhibit techniques; skill in soliciting materials and money; good health; and the ability to handle a canoe.”^[8] Thus, two courses covering the fundamentals of museum work (minus the canoe) were created, one in Iowa and the other in Pennsylvania. In 1907 in Iowa City, Homer Dill, an anthropologist and taxidermist, set up a “Taxidermy and Plastic Art” teaching lab and course at the University of Iowa Museum of Natural History. His students went on to direct natural science museums in Denver, Ann Arbor, and Minneapolis. A year later in Philadelphia, Sara Yorke Stevenson, curator at the University of Pennsylvania Museum of Archeology and Anthropology and an expert on ancient Egypt, taught a course in museum work at the Pennsylvania Museum and School of Industrial Arts, now The University of the Arts.^[9] Her course emphasized Greek, Roman, and Egyptian antiquities and their classification, as well as techniques for educating the public about these artifacts.

Demand for the fledgling museum training courses was high. “We cannot furnish enough graduates to supply the demand for curators and other workers,” Dill reported to the AAM.^[10] Yet, collectors and other prominent citizens who continued to found museums had little interest in training a workforce. Dill, Stevenson’s, and others’ efforts were discontinued. Throughout the next decades, seasoned museum workers remained in such scarce supply that, in its first code of ethics, AAM warned museums not to steal employees from another institution without the prior consent of the director. “A museum may not properly offer a position to an employee of another museum with which it has regular and intimate relations without having first notified the director of its intentions to do so.”^[11]

In the 1920s, two charitable foundations—the Carnegie Corporation and Rockefeller Family Foundations—advanced the cause of training museum workers. In face of accusations of their undue political influence on

educational institutions like libraries and museums, these foundations realized the value of an autonomous organization of museum workers. In 1923, the Laura Spelman Rockefeller Memorial Foundation gave AAM its first grant which was soon followed by support from the Carnegie Corporation. This support launched five activities that helped to establish a collective “museum sense” of professional practice, laying the groundwork for many of the practices embraced today by museum studies departments. They were: 1) a code of ethics; 2) a monthly journal called *The Museum News*; 3) a partnership with the National Park Service (NPS) to establish trailside museums (nature centers) to teach visitors about flora, fauna, and geology; 4) training programs; and 5) data gathering.

American Association of Museums’ 1925 code of ethics—the field’s first such guidelines—emphasized the public function of museums, noting that “the life of the museum worker, whether he be a humble laborer or a responsible trustee, is essentially one of service.” The code also promoted the virtues of loyalty, sincerity, tactfulness, and courtesy in the workplace, warning that “jealous acts, gossip, inquisitiveness, sarcasm, practical jokes, while often thoughtless, are always uncharitable.”^[12] Despite the ethical code, early issues of *The Museum News*, edited by Harold Madison, director of the Park Museum in Providence, Rhode Island, often printed gossip items. These included betrothals, summer vacations, and other life events of AAM members. However, the journal also provided short articles on new acquisitions and new kinds of educational programs offered at member museums and announcements of the availability of equipment, such as cases, shelves, collecting jars and the like. *The Museum News* offered tips for providing better public service, including the advice to let visitors touch objects when possible, perhaps the first iteration of the interactive education movement that decades later would become a serious subject of study in many museum studies departments.

The NPS trailside museum initiative was an important development because it represented the first coordinated effort between museum workers to develop a cohesive group of museums with similar styles of architecture, display, and educational interpretation. Lessons learned from establishing the first trailside museums inspired the first museum exhibition design manual, written in the late 1930s, by Ned Burns, head of the NPS Museum Division.^[13]

The Carnegie Corporation, headed by Frederick Keppel, a former dean at Columbia University, directly helped to advance efforts to train museum workers. Keppel was a proponent of adult education, in vogue because of the rush of non-English speaking immigrants into American cities. Possibly influenced by the work of John Dewey who was on Columbia’s faculty while Keppel was a dean there, Keppel believed that museums were ideal places to expose America’s adult population to higher cultural

values. Keppel began by training a museum workforce, sponsoring museum workers to travel to Europe to study the museums there. He then steered support to the first sustained museum training course in the country established in 1921 at Harvard University by Paul Joseph Sachs, son of Samuel Sachs, financier and founder of the banking firm Goldman/Sachs.

The Harvard curriculum emphasized materials, chemistry, application techniques, and new restoration technologies like x-ray equipment. Sachs' famous course "Museum Work and Museum Problems" covered not only art restoration, but museum history, philosophy, and management. He stressed that his students needed "educated eyes" in order to observe artwork closely and recognize the telltale flourishes of important artists. Sachs forged alliances between his students, the AAM (he served on its board) and the inner circles of the art world. Sachs "insisted that the museum must remain 'firmly in the control of a trained elite, [which would] maintain standards of quality independent of the contingent values of daily life.'"^[14] His illustrious disciples went on to lead America's best-known art museums, including the Museum of Modern Art, the St. Louis Art Museum, and the Toledo Museum of Art.^[15]

While the Harvard museum course focused on applying the values of connoisseurship to the nation's elite art museums, three contemporaneous training courses in the United States emphasized other areas of the museum field. In 1923, at the Newark Museum, Louise Connolly initiated a program that trained primarily young female apprentices in library work and museum education. Two members of the first graduating class of the Newark program—Dorothy H. Dudley, registrar at the Metropolitan Museum of Art, and Irma Bezold Wilkinson, registrar at the Museum of Modern Art—went on to write the first manual of standard techniques in collections documentation.^[16] From 1926 to 1929, Laura Bragg, director of the Charleston Museum (the nation's oldest museum) worked closely with AAM to pioneer a summer course at Columbia University in New York that included an apprenticeship in Charleston. Its goal was to emphasize the community educational role of museums and, in Bragg's words, "to make clear the ideals of the modern museum and the potential scope of its activities and influence."^[17] Starting in 1929, with funds from the Rockefellers, the Buffalo Museum of Science trained museum workers in the design and construction of natural science dioramas and exhibitions, including those at NPS trailside museums. This program was run by longtime AAM board member Chauncey Hamlin as well as Carlos Cummings who went on to write a classic museum text that compared world's fair displays to museum exhibitions.^[18] Museum training courses were also founded in Europe and South America during this era.

As trained men and women found employment in museums, the field gathered and analyzed data to guide their work. Until the 1920s, the majority of written

materials available to museum workers consisted of reams of technical information on taxidermy techniques. A perusal through AAM's 1928 *Bibliography of Museums and Museum Work* reveals only one article (by John Cotton Dana, director of the Newark Museum) discussing the value of public service. The majority of articles are on the details of taxidermy. Carnegie now began to fund research projects to cover other subjects, including the first studies of museum fatigue. From 1924 to 1928, Yale University psychology professors, Edward Stevens Robinson and Arthur Melton studied how visitors used exhibits, with an eye to creating environments and buildings that would be less tiring and more invigorating.^[19] Their work influenced directors to advocate for less cluttered displays and more comfortable viewing galleries. In 1928, Carnegie underwrote the first intensive cross-comparative study of museums. Paul Marshall Rea, a former director of the Charleston Museum, studied 104 museums and compared attendance and population data for their locales. He produced a dense study with 150 pages of elaborate logarithmic calculations and suggested such innovations as branch museums (urban institutions opening branches in outlying areas) and other cost efficiencies.^[20] Museum training and research programs were largely discontinued during World War II, when museums, like the rest of the nation, focused on the war effort. Yet these foundational efforts framed the importance of professional conferences and networks, publication of data and information, and training courses to advance and improve museums.

MUSEUM STUDIES IN THE SECOND HALF OF THE TWENTIETH CENTURY

After World War II, interest in training museum workers grew significantly. Through the Commission for the Protection and Salvage of Artistic and Historic Monuments (known as the "Roberts Commission" and housed at the National Gallery of Art), American museum specialists traveled to postwar Europe to assess the damage war had levied on the continent's monuments, masterworks, and archives. These specialists included Paul Sachs and many of his former students at Harvard. The Commission was named for Owen Roberts, Justice of the U.S. Supreme Court. With fresh memories of the damage World War II had wreaked on Europe's cultural landscape, museum directors from throughout the world founded international organizations like UNESCO and ICOM (International Council of Museums), dedicated to the protection and advanced public understanding of the world's cultural and education heritage. The need for training museum personnel at all levels was a significant topic of discussion, "enshrined in the basic charter setting out ICOM's role, with particular reference to the objectives of UNESCO."^[21] "If we must have museums at all in the postwar world"

declared Metropolitan Museum of Art director Francis Henry Taylor in 1945, then they “desperately . . . need to be overhauled and reorganized. But this overhauling . . . must be intellectual as well as physical.”^[22]

One urgent necessity was the training of personnel to manage and care for museum collections, a process that was becoming increasingly specialized. Until World War II, recordkeeping had primarily been the responsibility of curators, often referred to as “keepers,” a title still used in Great Britain. As the postwar examinations made abundantly clear, museums around the world had “kept” collections, but had largely neglected to care for them.^[23] Collections documentation systems had existed since the 1910s. But the first coordinated collections management and care training efforts did not begin until the second half of the twentieth century. In 1955, at the New York State Historical Association in Cooperstown, Paul Sachs’ former students, Sheldon Keck and Carolyn Kohn Keck taught the first course in painting conservation. In 1959, Sheldon opened the first training program for art conservators at New York University. Other training labs were founded at the University of Delaware (1951) under the tutelage of historian Charles Montgomery and Oberlin College (1952) by conservator Richard D. Buck. Much of the impetus for delegating this work to a specialist came from the rising value of art and the increased number of traveling exhibitions.

Americans were also traveling in greater numbers, due to the postwar economic boom and greater focus on leisure time activities. Outdoor museums like Colonial Williamsburg and those run by NPS began to develop educational programs for families and produce manuals for workers in how to create these programs.

Freeman Tilden’s classic guide to educational interpretation at historical sites, *Interpreting our Heritage*, was released in 1957 and is still a benchmark in the field.^[24] Other museum trends, especially in exhibition design, were analyzed in the field’s first independent journal, *Curator*, founded in 1958 and published by the American Museum of Natural History. In 1959, Edward Alexander, one of the twentieth century’s most prolific writers on museum history, founded the Seminar for Historical Administration at Colonial Williamsburg. Like museum training programs before it, the purpose of the summer-long seminar was to address the “critical shortage of adequately trained personnel . . . to staff [museums].” Alexander’s curriculum included courses in museum history, educational interpretation techniques, administration, and how to conduct research.^[25]

Increasing university resources and new government agencies led to a boom in new museums on campuses and in cities during the 1960s, and an expanded interest in developing resources for those wishing to work within a growing sector. The Smithsonian Center for Museum Studies was founded in 1965, along with university-based training programs including the University of Wisconsin

in Milwaukee (1963), Cooperstown Graduate Program (New York, 1964), and the Museology program at the University of Leicester (United Kingdom, 1966). In 1969, ICOM’s newly formed International Committee for the Training of Personnel (ICTOP) held a major symposium on the professional training needs of museum workers at the University of Leicester. Among the issues explored were the lack of recognition within universities of museology as a valid academic discipline and the need for an internationally recognized basic syllabus and training standards.^[26] Under the guidance of Smithsonian specialist Nancy Fuller, the initial ICOM Basic Syllabus for graduate-level Professional Museum Training was published in 1971. The components and emphasis of this syllabus has been revised several times in the ensuing decades to assure that it reflects changes in the museum field.

During the 1970s, despite the international calls for a standardized curriculum, in the U.S. universities founded museum studies training programs to meet local and regional needs. Like the early individualistic museums, discussed above, these programs were eclectic and reflected the expertise and strengths of their founders as well as their trends in their locales. John F. Kennedy University (JFKU)’s Department of Museum Studies, founded in the San Francisco Bay Area in 1974 by Deborah Kirschman, drew on the then-unique community focus of the Oakland Museum as well as the experimental educational work of the Exploratorium, Berkeley Art Museum, and San Francisco Museum of Modern Art. The George Washington University (GWU)’s program, founded in Washington, D.C. in 1976 by a committee of professors in the Art History, Anthropology, and American Studies departments, distinguished itself in museum education, curriculum development and law, drawing on its proximity to the Smithsonian Institution. Both JFKU and GWU created professional journals to disseminate current museum research to others in the field. John F. Kennedy University’s Museum Studies Journal was discontinued in 1988. Another early program was founded at New York University in 1977 by Flora Kaplan. New York University’s program emphasized art history, conservation, and exposure to the diverse landscape of museums throughout New York City. University of Delaware’s program (1972) emphasized history and the decorative arts; Bank Street College’s program (1978) was known for embracing progressive educational techniques.

These programs, as well as others forged during the 1970s, benefited from the large increase in philosophical and practical guides to museum work. Texts published during this era addressed a range of subjects, from the expanding role of museums’ education departments, to calls for accountability that were emerging from the growth in government funding, to modern architecture, to the future of museums in uncertain times (a recurring theme in the field of museum studies). They included such

seminal publications as Ellis Burcaw's *Introduction to Museum Work* (1975); Barbara Newsom and Adele Silver's *The Art Museum as Educator* (1978), and Edward Alexander's history text *Museums in Motion* (1979). The growing numbers of disparate museum studies programs led to the founding of AAM's Museum Studies Curriculum Committee in 1973 (now known as the Committee on Museum Professional Training [COMPT]). Like ICTOP, COMPT members have continually argued for standards and rigor within curriculum and scholarship. As Patrick Boylan, chairman of ICTOP, noted in 1987: "There is [still] no unanimous view about the form, content or extent of training for museum staff."^[26]

Museum studies changed radically during the 1990s. The popularity of cultural and postcolonial studies in universities, coupled with high-profile controversies at several museums over the content of exhibitions, led to intensive analysis of the politics, ideology, and values inherent in museums by scholars (for example, Tony Bennett, James Clifford, and Donna Haraway). With museums reeling from the Robert Mapplethorpe and *Enola Gay* scandals on one hand, and the passage of the Native American Graves Protection and Repatriation Act on the other, art historians and anthropologists posed difficult questions. What was the relationship between cultural displays and the cultural assumptions of the people who created those displays? How had the museum acquired their collections and who really owned those collections? Who was the museum really for?

Concurrently, the growth of children's museums and interactive science centers led to intensive attention to the educational theories like multiple intelligences (Howard Gardner), and constructivist learning (George Hein). With interactive displays seemingly blurring the lines between education and entertainment, academicians accused museums of "dumbing down" while educators defended their attempts create to more accessible programs. More debate ensued as government cutbacks and financial retrenchment led to increased calls for accountability, ethical decision-making, and greater attention to the museum-going public. Key texts by scholars like legal expert Stephen E. Weil and educational researchers John Falk and Lynne D. Dierking advanced the thinking in these areas. In his edited book, *The New Museology*, Peter Vergo, an art historian and theorist at England's University of Essex, published a collection of essays that aimed to open the door toward a "radical reexamination of the role of museums within society."^[27] These growing and sometimes bitter debates contributed to new research and ways of thinking about the core issue that concerns museums: the improvement of museums. All of these debates were undertaken in museum studies curriculum and literature. Dissertations on museums grew in number, as did conferences, symposia, and workshops.

Toward the end of the 1990s, the spread of digital technology radically impacted museum studies. In the late 1990s, museum studies departments at JFKU, GWU, and Harvard University offered the first courses in museum studies and technology, taught respectively by Richard Rinehart, Kym Rice, and Katherine Burton Jones. This area of study has grown substantially in the last decade, with attention paid to researching how to create more accessible online databases, caring for digital assets, communicating through online social networks, developing technology in exhibitions, and so on. Another result of online technology has been the spread of distance-learning and online courses in museum studies.

Despite or perhaps because of the growth of museum studies as an area of scholarship and professional training, the debates continue. Is museum studies a subset of larger academic disciplines or is it a field in its own right, meriting a separate Ph.D.? Does museum studies curriculum really train future professionals to successfully lead museums in all of their complexity? Are there too many museum studies programs and initiatives for a relatively small sector of the nonprofit economy, or are there not enough for a creative industry that continues to found new institutions and create new initiatives?^[28] Would museum studies programs benefit from industry accreditation standards, or would these standards confine a curriculum and area of study that thrives on adapting to rapid changes in the marketplace? All of these questions and others point to a robust future for the field of museum studies.

Museum Web Sites and Digital Collections

David Bearman

Jennifer Trant

Archives & Museum Informatics, Toronto, Ontario, Canada

Abstract

Museums adopted the Web early, building on their experience with videodisc and CD-ROM publications in the 1980s and early 1990s. From the first, they introduced experimental features including visitor feedback, three-dimensional (3D) walk-throughs, and deep coverage targeted at niche audiences. Only with the maturation of the genre did they routinely have basic hours and location information for visitors as part of their sites. Consistently, museum use of the Web has been programmatically driven, emphasizing exhibitions and events, rather than collections databases and privileging browsing over site-searching (though supporting search engines). Over the next years, museums will increase the amount of location-based content delivery and aim content at cell phones, pdas, and similar devices being carried by their potential audiences.

INTRODUCTION

The World Wide Web (the Web) has provided an easy way for museums to reach their many audiences, publishing a range of materials about their institutions and collections, and creating spaces for their varied constituents to engage with each other, and with the content of collections. Following its release in 1993^[1] the Web was rapidly adopted by museums (a development traced in the proceedings of the Museums and the Web conferences (1997–). Today, 15 years after its release, having a Web site is considered a necessity by museums. This rapid adoption of the Web by museums reflects the fit between museum needs for widespread dissemination of multimedia content and the ease with which the functionality embodied in the Web supports programmatic needs.

Museums care for information as much as they care for collections. The Web enabled relatively easy publication of complex documents, richly illustrated in color (something that the economics of print publication was making more and more difficult). The broad reach of the Web enables contact with both local constituencies, and international networks of potential tourist visitors and subject-specialist scholars. Broadcast of basic information about the institution (such as location, hours, and exhibition program) and narrow-cast of in-depth information for particular audiences (such as teacher-packets and interpretive programs for schoolchildren) are enabled by the same technology.

Museums were well positioned to take advantage of the Web through early experiments in multimedia. They remain leaders in the use of social computing technologies, because of the true fit between these tools and the desire to engage communities—based in part on the new museology.^[2]

HISTORY OF MUSEUMS ON THE WEB

Background

Museum adoption of the Web in the mid-1990s built on a decade of museum experiences with hypertext, networking, and multimedia. By 1993, museums were widely exploiting stand-alone interactive image and text on kiosks within the museum, often using videodisc or CD storage.^[3] While these technologies enabled distribution outside the museum on fixed digital media, the reach of these publications was extremely limited when compared to the near ubiquity that the network now provides. Authoring tools were proprietary and often difficult to use, and run-time environments were closely prescribed and often hardware-based.

Museum networking on private, proprietary connections had been available in the 1970s, and national networks (such as the Canadian Heritage Information Network) and regional ones (such as the Museum Computer Network GRIPHOS application), had been built. But prior to the Web, networking databases was expensive, limited to text only, and for institutional rather than public needs; early French experiments with public access to Minitel reached out more broadly. Immediately prior to the advent of the Web, in the late 1980s and early 1990s, open protocols developed for access to (predominantly text) files over the Internet—such as archie [for ftp] and gopher for files—were experimentally employed by some museums. The most radical aspect of the Web was that it enabled true multimedia. While initially only text and image, for a community that had struggled with side-by-side monitors for text and image videodisc display, and hardware-dependent CD-Rom authoring, this was a major breakthrough.

Early Cultural Web Experiments

Most museum technology professionals were probably introduced to the possibility of networked access to cultural heritage information by the Library of Congress' exhibit of *Treasures from the Vatican* which was delivered over the Internet^[4] from January to April 1993, even before European Organization for Nuclear Research (CERN) board decided to make the World Wide Web publicly available, using the alpha release of the first popular Web browser, Mosaic.^[5] A few might even have seen the exhibit of Soviet materials released in the previous year, before any inkling of the Web had spread beyond CERN. Outside of academia, uptake was only slightly slower. The French Ministry of Culture site on the Lascaux caves, which first appeared late in 1994 played an important role in alerting generalists to the benefits of publishing cultural content on the Web.^[6]

Some museums in the academic sphere were introduced to the Web before commercial browsers made their debut in late 1994. Teaching and research collections took the lead by implementing Web access to their existing databases. As early as August 1993, the University of Illinois's Krannert Art Museum launched a hypermedia exhibit on the Web; the University of California at Berkeley, Museum of Paleontology had a site underway by September which by year-end included a walk-through of the Dinosaur halls and an interactive guest book. The University of Virginia Rosetti Archive had launched an experimental Web site with digital collections, exhibits, and educational materials by the spring of 1994. The Perseus Project, a digital library that was under development since the spring of 1987, was quick to try out Web-based access methods.^[7] These early scholarly initiatives pointed out a new audience for museum collections content. In January 1994, the Exploratorium became the first nonacademic museum site on the World Wide Web.

However, the Web was not seen as the only viable solution to networked access to linked image and text for a few years. In late 1994, when the Getty Museum Educational Site Licensing Project launched its competition for University participation in a museum image sharing project, one element in evaluation was whether the participants had the capacity to develop applications to deliver networked multimedia. Several contenders had existing, non-Web, applications that were in experimental use, and were selected in part based on that. However, by the time the first MESL applications appeared a year later, all but one of the Universities employed Web protocols rather than the special solutions each had been expected to have to create to deliver multimedia over the Internet.^[8]

Early Museum Web sites

It is tempting to paint a path from simple to complex museum Web site—from brochure, to exhibit, to shop, to

online collection, to social network, to semantic Web—but the history of museum use of the Web is not linear. Many museums first saw the Web as an experimental space in which they could develop hypermedia and test very demanding digital delivery scenarios. It was only with the broad public popularity of the Web that museums came to realize that their sites ought to include basic “brochure” information.

It is still surprising to many that the first sites built by museums often lacked such fundamental elements as museum hours (and especially location information), and that some of the earliest museum Web sites included collections, exhibitions, educational interactives, and even what we would now think of as social networking features.

The citation given by GNN (The Global Network Navigator) in 1994 to the Paleontology Server at The University of California Museum of Paleontology^[9] read:

The server is an interactive natural history museum available over the Internet. This museum without walls is well organized and makes interesting use of large graphics. You can learn about phylogeny, the “Tree of Life,” or examine photographs of Great White Sharks off the California coast, which proves that paleontologists study living things as well as fossils.

Other early adopters included the Museum of Natural History, London^[10]; the Science Museum, London; and the Canadian Museum of Civilization.

MUSEUM PROGRAMS ONLINE

Web pages of museums have evolved to reflect the range of museum programming. An informational core, which presented the museums' physical reality in cyberspace, soon formed the required “brochure.”^[11] The basic elements of a museum Web site included information about the museum, location, maps and admissions, details of exhibits and current events such as tours, a profile of the collections, possibly with some highlights, perhaps some detail about the institution's history, a welcome from the director, information about museum membership and giving to the museum, facilities rental, and the museum store. Extended features often centered around special exhibitions, and then were “archived.” Education materials, for teachers could be exhibition related, or related to the permanent collection. If this sounds like a reiteration of the physical museum, in many ways it was. Each department found its place on the Web, and early museum sites often reflected the concerns of their internal leads.^[12]

Online Museum Exhibitions

As with the physical site, most museums' preferred way to display their collections online has proven to be as part of

an online exhibition. The fundamental advantage of the Web is that it offers opportunities for additional content and broader audiences. From the first, exhibitions were about more than simply showing museum objects with juxtaposed text; the object was to create an experience in multiple sensory dimensions, not unlike that of entering a real-world exhibit. In early 1994, when “fast” Web access meant someone was using a 14.4 mbps modem, the Smithsonian’s “The White House Collection of American Crafts,” (which opened on the Web on April 25, 1994), included extensive video and audio clips of the curator talking about selected pieces and handling them in ways that would not be possible during the exhibition.^[13] In addition, each artist was asked to answer a series of questions about their work, which was not part of the exhibition itself. An important element of the exhibit, novel at the time, was what we would now think of as a “social networking” feature that allowed visitors to add comments to a comment book.^[14]

In 1995, the Museum of Modern Art, New York (MOMA) was developing online exhibitions to accompany many of its physical shows. Like many museums, it still lacked an infrastructure to support its online activity so sites for “Annette Messenger,” “Video Spaces: Eight Installations,” and “Mutant Materials in Contemporary Design” were hosted for MOMA by the School of Visual Arts.^[15]

Within a short time, museums developed a range of interpretive materials to augment online exhibits. These were often aimed at specific niche audiences, such as games for children, pre- and post-visit guides for families, learning packages for teachers, and extensive scholarly research pathways, and have become a standard way both to market the in-house show and to extend its useful lifetime. Most museums today will have an online surrogate or augmentation of current exhibitions on their sites. In addition, many will provide access to past exhibits, which of course are no longer accessible in the physical world, even if they are not truly serving a guaranteed, permanent archival function.

Substantial research has been undertaken on storytelling and narrative presentation online in support of museum exhibitions. But museums are aware that their efforts are often subverted by the fact that their visitors do not “enter by the front door” and read the linear script as written by curators, but rather reach the museum by search engines taking them deep into the interpretive narration.^[16]

Online Events

Museums have found the low cost of entry to broadcasting over the Internet highly attractive, in part because of their interactive capability (though the facility for narrow-casting provided by Web-based programs is equally important). Using the network to bridge geography is a common

strategy, whether this is the virtual reuniting of a dispersed work, or the creation of a real-time multipoint event. As an example of the latter integrated into a museum’s educational program, from February 11–21, 1997, the Exploratorium site provided live interactions with astronauts servicing the Hubble Space Mission. In two shows daily, they combined live feeds from the orbiting shuttle, science demonstrations, videoconferencing with researchers across the country, and questions from the audience.^[17] Since then, at the Exploratorium and many other science museums worldwide, regular interactions between scientists and school children via Webcasting, have become standard features of museum programming. At the Natural History Museum (London) these Web-based features now occur daily.^[18]

Social Experiences

Museums envision themselves as gathering places designed to encourage thinking, generate dialogue, and occasionally create controversy. So the social potential of the Web was seen as crucial to its museum implementations long before the mainstream invented the rubrics Web 2.0 and social computing. Partnerships with schools were the first territory explored by museums, and this rapidly led to the teachers, and then the students, contributing content back to the museum.^[19] Applications that enabled visitors to provide their views followed swiftly.^[20]

By 1997, museums were inventing mechanisms for user feedback missing from the Web at large. Web designers for the Smithsonian Institution’s *Revealing Things* exhibit envisaged users as both “designers of their personal exhibits” and “contributing objects and stories to the presentation. . . chang(ing) the experience for themselves and others.”^[21]

Early observers recognized that user-generated (or user-contributed) content and the interaction of the Web would challenge the authority of museums. Some celebrated that,^[22,23] while others were concerned. The resulting dialogue clarified the differences between authority and authenticity and helped museums position themselves vis-à-vis their varied publics.^[24]

Some museums, led by the National Museum of the American Indian in Washington and Te Papa in New Zealand—two national institutions that were first opened during the “Web-Age,” began to construct architectures that enabled them systematically to obtain and use the insights of indigenous informants to bring a perspective from within the societies that originally created artifacts to bear on museum documentation.^[25] The Encyclopedia of New Zealand encourages and incorporates user-contributed content.^[26]

Because one of the problems museums face is that of describing the objects in their collections, and providing access to them in ways that visitors find useful, engaging volunteer catalogers over the Internet was explored in the 1990s. In the MESL project, the Fowler Museum’s

experience of obtaining remote assistance in describing part of its African collection from Columbia University was held up as a justification for the effort involve in putting collections online.^[27] The Fine Arts Museum of San Francisco had early success with volunteer keywording of its Thinker database.^[28,29] But action came with the success of social tagging at del.icio.us and flickr in 2004. Organized investigation of the potential for folksonomy in the steve. museum project^[30,31] coincided with implementations of nonresearch taggers, the most extensive of which is at the Powerhouse Museum in Sydney.^[32] Early findings are that many people find it rewarding to tag, and will generously give their time to museums if asked. The resulting tags are mostly relevant and not terms that the museums have in their own documentation.^[33,34]

Museums have also been attracted by the engaging power of serious games, especially as a means of attracting and keeping the attention of younger audiences and people who might be alienated by more traditional methods of teaching. An excellent example, Launchball at the Science Museum of London, winner of several “best of the Web” awards in 2008, including one at the South by Southwest Interactive Festival.^[35] Similarly, the power of providing visitors with sophisticated tools with which to construct their own meanings and publish them to the Web, has been successfully used by museums to engage visitors, as with the film editing widget at the American image exhibit of the Maxwell Museum of Anthropology.^[36]

Museums are also finding that they can meet potential audiences in engaging social spaces created by others, including commercial services. Social computing spaces such as FaceBook, Flickr, and YouTube are attracting museum attention and programming.^[37–39]

Virtual Experiences

Museum exhibitions are three-dimensional (3D) installations designed to offer context to objects so that they may be better understood. It is not surprising, then, that efforts to create 3D environments on the Web attracted museum interest from the first. In 1993, the University of California Berkeley Museum of Paleontology demonstrated the potential of exhibition walk-throughs. By 1997, museums were regularly providing remote visitors with 3D experiences over the Web—both walk-throughs of spaces, and 3D models of artifacts.^[40,41] Quickly, though, the community realized that we didn’t need elevators in Web museums; the logical models of museum information-space were more effective when they didn’t mirror the architecture—and historic organic growth—of physical museum spaces.

Early reports featured natural history educators using 3D modeling to teach morphology, registrars providing information to potential researchers prior to shipping a fragile item, and school teachers exciting students into careful observation. Reconstructions also tested historical hypotheses.^[42] The Science Museum in Milan provided

remote 3D access to “working” models of Leonardo Da Vinci’s inventions, including those never built in the real world, in 1999, and allowed avatars representing individuals logged in from remote locations to “join” each other in an experience^[43,44] similar to that museums are now exploring virtual worlds such as Second Life.^[45]

Museums have also successfully used the Web to offer a window onto otherwise “back-room” museum processes. Projects like those that chronicled the lengthy conservation of works of art at the Minneapolis Institute of Arts^[46] helped museums demystify some of their professional processes.

Some museums (along with universities, governments, and many other institutions) have taken up a virtual presence in these virtual worlds today. Often, they have done so, like the Exploratorium, explicitly in order to provide experiences that are not possible in the physical world, such as experiencing Brownian motion by riding on a dust particle.^[47] Others are content to see virtual worlds as useful because avatars provide an emotional extension of humans into the virtual world and thereby enhance interpersonal communication that might otherwise occur through online chatting or bulletin boards alone.

Evaluators are still trying to determine when these kinds of experiences were necessary, and when they might be simply entertaining, or even distracting. Investigation about how to bridge the physical space of the museum and the virtual space of the Web is ongoing.^[48] Findings have often seemed counterintuitive; for example, after years of experimentation, museums have discovered that bookmarking, per se, is not something that visitors do at museums, though museum professional repeatedly hypothesized that it would be a highly rewarding application.^[49]

Searchable Collections

Although “virtual collections” and “digital museums” are concepts that are often associated with museum use of the Web, they have their roots, and their primary appeal, outside of the museum culture, in broader society and in academia. Many early “virtual museums” such as the Virtual Louvre or the Artchive, were creations of individual enthusiasts rather than institutions.

Online catalogs have not been the primary goal of museums on the Web, in direct contrast to libraries, who have seen the OPAC as the first point of contact with their online public. Some institutions with close academic ties, particularly if their collections were assembled for research or teaching, made their collections catalog searchable on the Web early. For example, the American Museum of Natural History had its Library catalog online in 1996.^[50] The Fine Arts Museums of San Francisco (FAMSF)—an early adopter of digital imaging technology—had over 65,000 works online for viewing at its “Thinker” site in 1996,^[51] and encouraged its Web visitors to “be the curator!”

The FAMSF site included teachers' guides and online tours of temporary exhibitions as well.

Museum collections catalogs are difficult for the nonspecialist to interpret and are often better suited for expert use. These text databases often only include rudimentary data often without any images, or with only one relatively low-resolution image. Because the primary audiences museums wish to reach through the Web are not only "researchers" but potential visitors, additional contextual and interpretive materials have priority.^[52] One approach to making the museum catalog more accessible has been to link it to familiar interfaces. Integrating museum databases with other sources of information, especially to enable graphical displays that are intuitive to end users, was a desire of museums before the Web and suggested as an early objective of Web implementations;^[53] with the advent of Ajax and techniques for Web mashups, integrating museum data with data and tools from other sites, there have been successful implementations in museums. By dragging multiple images from the public sources on the Web, researchers have been able to recreate 3D renderings of historical sites as if they were flying through them.^[54] Many "museum-like" applications, such as the mashup (combination) of ornithology data with map coordinates, have emanated from university laboratories.^[55]

Still in its infancy, but growing quickly, geo-encoding of museum collections enlists the potential of location-aware information delivery based on open APIs (Application Programming Interfaces) to put museum objects where the audience is physically, rather than expecting the audience to come to the museum. By geo-encoding the locations of important events in the life of an object into its digital record, museums use the same Web-based infrastructure that is evolving to tell people in passing cars about local restaurants and other commercial offerings, to inform them about the cultural artifacts that are native to the area in which they find themselves, even if these are in museum collections thousands of miles away. This has potentially revolutionary consequences for how people relate to the spaces in which they live, and for museums it has the capacity to "turn the museum inside out" and show its collections in the contexts in which they were made, used, or collected.^[56]

Collecting and Preserving

Museums, particularly art museums that have contemporary culture as part of their collecting mission, or those that are dedicated to understanding contemporary events, such as science centers, face a special challenge since they not only need to use digital methods to provide the public with access to their collections, but also are challenged to collect and exhibit digital works.

Art museums, self-consciously collecting *avant garde* digital art, were the first to encounter the challenges of

exhibiting and preserving born-digital collections.^[14,57,58] Some early examples, such as "Gallery 9" as of December 1998, can still be seen at the Internet Archive.^[59]

Increasingly science museums and even history museums are being challenged to collect digital artifacts as these artifacts have an impact on everyday life. A community museum, might, for example, have to collect digital artifacts in order to document community involvement in a planning process conducted using environmental impact mapping in a collaborative Web space.^[60] This process, conducted over many months, relied on visualization tools, models, and data that were specific to the community, and logged hundreds of citizens participating in the discussion and illustrating their points by digitally generating representations of different possible futures. Science museums which are experimenting with making science news feeds a part of their on-site exhibition, such as the Minnesota "Science Buzz" project, or which are creating opportunities for visitor feedback by cell phone as at the Liberty Science center, will need to consider just what place an archival record of these interactions has in documenting the museum programs.

Ongoing digitization programs are retrospectively creating digital versions of photographic surrogates kept by museums for identification and documentation purposes. But while in libraries retrospective digitization is sometimes cast in terms of preservation (for the digital copy holds the same informational content as the original), in museums digital surrogates will never take the place of original museum artifacts. Although digitization projects in museums are primarily about access they have spin-off preservation benefits by reducing the impact of repeated handling for reference purposes, and have, unfortunately, also sometimes left us with the only copies of works once in museums but lost through war or natural disaster.

IMPACT ON MUSEUMS

In its brief 15-year history, the World Wide Web has already had significant impact on museums as institutions.

Sectoral Identity: The Museum Domain

At MW97, Cary Karp proposed that museums ought to have a place in the Internet domain name system.^[61] By 2000, he had led ICOM and the J. Paul Getty Trust in an effort to obtain a high level domain for museums in the belief that high level domains would proliferate and that a distinctive one for museums would serve their needs to be recognizable in Web space.^[62,63] Although widely publicized in the museum community, the new top level domains have not had the impact socially that was expected in 2000. Museums, which generally maintained their identities in "dot org" or "dot edu" space, have not

made the switch to “dot museum” in appreciable numbers. At present it seems unlikely that they will because newer top level domains, introduced after the national domains and the three original ones for commerce, civil organizations, and education, have not captured the popular imagination in other sectors either.

Outreach

Though the distinction of museums as high level domains did not enhance their sectoral visibility, Web technologies are being deployed successfully to raise the profile of individual institutions and their programs. Many museums are using RSS (really simple syndication) to narrowcast the contents of their sites to those with specific interests in their topic. By tagging their content with a variety of highly specific descriptors, and using RSS to distribute a feed of news items, they enable aggregation and representation of museum content in diverse contexts. The 24 hr museum, now culture 24, aggregates news about U. K. museum activities, and presents it as an integrated museum-related RSS feed.^[64] RSS has also been used to create content streams that are used to animate museum exhibition environments.^[65,66]

Some museums are encouraging viral marketing^[67] in order to build mini-communities of interest around particular parts of their content. Museums are actively engaged in blogging, podcasting, and even in posting videos to YouTube. And the “fans” of museums on social sites such as Facebook, are being used to promote its activities to their friends.

Like other institutions influenced by academia and libraries, museums were caught off-guard by the overwhelming success of search engines. By 1997, reports already revealed that while museums were expending much energy in authoring visually and intellectually enticing sites, their content was organized narratively and linearly while most of their users were finding specific content in searches and then linking directly into the museum site at the level of that content. Museums have responded to their users “entering by the window rather than the front door” in several different ways. Some museums have taken great care to be fully available to search engines—hiring Search Engine Optimization (SEO) consultants, inviting crawlers, making metadata for the search engines to use, identifying resources with URIs and other digital identifiers, and attending to the requirement for persistent addressing. Others have become engaged with libraries and universities promoting the use of the Open Archive Initiative (OAI) protocols for harvesting museum collections data. The Consortium for Computer Interchange of Museum Information (CIMI) led a well-publicized effort to adopt OAI for museums, but the limitations of the Dublin Core metadata framework essentially defeated this effort, despite funded attempts to overcome them.^[68]

Some museums are watching carefully to see how the Semantic Web evolves and what kinds of discovery can be provided by geo-aware methods. When museums were first introduced to the semantic Web in 2002, the excitement level was high^[69,70] however as these technologies evolved and it became clearer that semantic Web accessibility of collections depended not just on metadata but on quite sophisticated metadata expressed in Resource Description Framework (RDF) with a defined ontology, the enthusiasm gave way, outside academic circles, to watching and waiting.^[71] In 2008, with the launch of some more sophisticated toolsets demonstrating the potential of semantic Web approaches, some cautious renewed interest is being expressed, but as always the barriers to museum making their collections available in this way are that they lack the resources and often the knowledge of their collections, to create the necessary metadata. Meanwhile, geo-aware devices in phones and automobiles, and an array of services that might be built upon these, are attracting significant attention in museums whose collections were gathered from locations around the globe and can often be best interpreted in those contexts, if they could be discovered there by tourists or locals.

Staffing and Resource Allocation

The Web has created new opportunities for museums to reach their audiences and conduct their missions, but it did so at a cost. In effect, each museum has now opened another branch. While early museum Web sites were often projects of one or two dedicated people (or even unauthorized “skunkworks”), increasingly museums have learned that their Web presence requires all the manpower and programming attention of a second venue.^[72]

Maintaining a quality Web site makes both technical and program content demands on the museum. Staff throughout the institution become responsible for updating the public face of their departments and programs as represented on the Web. Data that was created for internal purposes needs to be revisited and repurposed for public access. As information is created digitally for use in-house, on the museum Web site, in virtual exhibits and in syndicated content for “cultural events” sites and ticketing agents, the need to manage digital objects that can be reused for a variety of purposes increases. The technical sophistication demanded by such reuses has led museums to implement Digital Asset Management and Digital Rights Management systems in addition to traditional Collections Management Systems that keep track of the physical collection of the museum.

User expectations based on the evolution of nonmuseum Web experiences impinge on acceptance of the museum product and force the museum to continuously upgrade its capabilities and offerings. And requirements imposed by governments, for example to provide

accessibility to those with physical handicaps, now extend to online visitors.

Museums face the challenge of retaining skilled staff. In a project-driven culture, where much work is often outsourced developing institutional capacity is an issue. Many museums don't have programming staff on site and so are stretched to take full advantage of the potential of the Web.

Even maintenance becomes a great challenge, since the Web imposes a constantly changing technical requirement on the museum. Information technologies within the institution and servers providing access to the outside world must be maintained. Specialist staff must learn about online education, online fundraising, online publication, and other online programming skills. Technical standards that were optional for institutions without interconnections become mandatory. And in-service education becomes necessary. Ongoing venues for professional development include annual conferences such as Museums and the Web, the meetings and listservs of organizations such as the Museum Computer Group (United Kingdom) and the Museum Computer Network (USA), the Association of Science and Technology Centers, The Visitor Studies Association, and to some extent the work of the International Council of Museums' Committees on Documentation (ICOM/CIDOC) and Visual Information (ICOM/AVICOM). Emerging online communities of professionals include ExhibitFiles.org and conference.archimuse.com.

Business Models

In the early days of the Web, museums and other social institutions, wondered if it had income potential, and if so whether they wanted to exploit that source. Quite a few museums were caught up in the early widespread notion that the Web might be a source of significant new income. Museums lived through the dot.com boom and bust; while only a few (notably the Museum of Fine Arts Boston, museum shop^[73]) succeeded in making money from it, none went out of business as a consequence. However, some museums joined high-profile consortia with universities to provide online education, and these did collapse in the bust of 2001. Since then few museums have made online commerce a priority. However, most museum Web sites have e-commerce functionality (often delivered by an outside provider) to support basic store purchases, membership sales, and occasionally online ticketing. Although advertising emerged as a means of making income from the Web in the early twenty-first century, other than a few high-profile sponsorship relationships (such as British Telecom and Tate) museums have not introduced advertising on their sites. For the present, anyway, museums are treating the Web as a service to be provided for free and without commercial advertising, even when they charge for access to the physical museum and actively solicit sponsorship for on-site exhibitions.

Outside the museum community, museums are perceived to be making money from the sale of rights and reproductions; however, far from being a major source of new income, online licensing has become a cost-center for most museums.^[74,75] As well as requiring costly research in order to discover the rights inherent in collections, museums often pay fees to use materials online themselves. Efforts to make the works available under Creative Commons licenses or free to scholars have not proved very attractive to museum administrators, who, unlike their counterparts in libraries, have historically incurred high costs in making images available and recovered some of that cost through fees. Experiments with access for noncommercial uses at the Victoria & Albert Museum and The Metropolitan Museum of Art are, however, ongoing. The Creative Commons was not flexible in offering museums a license that worked for them, until the CC+ license of 2008, which some museums may now be ready to consider.

In 1997 more than 30 high-profile art museums joined to form the Art Museum Image Consortium (AMICO). The purpose of AMICO was not to earn income for the museums, though it developed a successful licensing scheme that ultimately recovered its costs of rights clearance (which are quite high for art of the past century), but to find a way to serve university and school students high-quality digital reproductions by reducing transaction costs.^[75,76] Its success attracted the Mellon Foundation which launched ArtStor, a program with similar objectives which subsequently absorbed AMICO and now licenses a collection of art reproductions (much not sourced from museums) to higher education.

Despite these experiments, museums have generally not followed either the commercialization route or the licensing route. The trend is toward more open access, with mission-related goals of accessibility and education guiding museums to make content available on the Web without restrictions, but within the context of museum programming rather than as discrete objects in searchable databases.

Issues Facing Museums Online

From the first, museums have been concerned that their move of programming to the Web increase opportunities for participation. Early implementations were highly sensitive to average slow access speeds and low resolution monitors, and present implementations avoid proprietary tools. The Digital Divide continues to echo in museum discussions. As public institutions museums don't want their choice of delivery channel to exclude users.

Using the Web in a socially responsible way has led museums to open themselves up to challenges to their ownership of objects in their collections (creating, for example, avenues that can be used by those claiming they

benefited from Nazi war loot), their interpretation of objects in their collections (enabling alternative accounts from aboriginal communities for instance) and ensuring accessibility.

Finally, museums are beginning to alter their measures of success. Instead of counting “visitors” to the museum itself, or to its Web sites, some museums are beginning to find ways to measure their audiences or impact even when the content of the museum is seen or used somewhere other than the museum site.^[77] It is likely that syndication of content on other nonmuseum sites, as the Library of Congress and Powerhouse Museum are now experimentally doing with photographs from its collections in the Flickr Commons,^[78] will become a growing trend. Museums are slowly ceding control of their content in order to reach audiences through as many channels as possible.

CONCLUSIONS

Museums have long used new media technologies, be they murals, dioramas, films, or interactive Web pages, to help explain the complexities of their collections to many diverse audiences. They publish a wide range of materials, from printed ephemera (in-gallery hand-outs) to scholarly tomes (exhibition catalogs), in a wide range of formats. From its outset, the Web has proven a suitable platform for delivering many types of information to many different users, and museums have adopted its many potentials. As the Web interpenetrates real space, with portable, geo-aware devices like the iPhone™, museums will find that it continues to serve their goals: engaging communities with collections and encouraging active learning and participation.

Museums

Leslie Madsen-Brooks

Boise State University, Boise, Idaho, U.S.A.

Abstract

Museums are diverse institutions—and grow more so. Few museums have remained untouched by shifting paradigms of research, education, and leisure activities. During the late twentieth century, museums increased their emphasis on their public educational missions. As part of these efforts, museums and related institutions, such as planetaria, botanical gardens, and zoos, are embracing new ways of engaging with audiences, for example through new technologies or during special events that emphasize civic discourse. Despite the opportunities offered by these new approaches, museums continue to wrestle with issues of funding and larger cultural politics.

INTRODUCTION

Museums are slippery institutions in that many of them are reevaluating their missions and redistributing their resources to meet the challenges of an increasingly urbanized culture, digital communications, and national and global environmental and cultural crises. This entry provides an overview of the state of museums in the early twenty-first century.

This entry begins with a definition of museums and a brief bit of museum history, then moves into more detailed descriptions of the contemporary functions of a museum: collections and research, exhibition and education, civic outreach, and leisure destination. There follows a list, with brief descriptions, of a dozen different types of museums. This entry then looks at current opportunities and challenges within the museum field—technology, civic discourse, funding, and politics—before concluding with an overview of professionalization processes. This entry is appended by a list of resources—professional organizations, books, journals, and websites—that allow for further learning about museums and the museum field.

WHAT IS A MUSEUM?

Definition

Museums are sites where objects, ideas, and cultural beliefs are represented and contested. More so today than in the past, they embody the intersection of expert knowledge with more local ways of knowing.

The International Council of Museums defines a museum as a nonprofit organization that conserves, studies, and exhibits “the tangible and intangible heritage of humanity and its environment” for the “education, study, and enjoyment” of the public.^[1] The U.S. federal

government, through the Museum and Library Services Act, defines museums similarly, requiring in addition a professional staff and regular public exhibitions.^[2] The American Alliance of Museums (AAM) Code of Ethics for Museums notes that their common denominator is making a “unique contribution to the public by collecting, preserving, and interpreting the things of this world.” The Code recognizes various types of museums, many of them places that those outside the museum profession might not consider to be museums, for example, botanical gardens, aquaria, zoos, and historic sites.^[3] The Institute of Museum and Library Services tracks 35,000 U.S. museums and related institutions—such as botanical gardens and aquaria—which the AAM estimates employ 400,000 Americans and generate 850 million visits per year.^[4]

HISTORY

The earliest “museums” were religious sites dedicated to the muses (mouseion) of ancient Greece. By 340 B.C.E., Greek philosophers such as Aristotle were founding lyceums to further scholarly study and discourse, and some of these sites were home to collections of plants and other biological specimens. Between about 200 and 60 B.C.E., the Romans became enamored of Greek statuary and art, and many public spaces as well as private homes in Rome featured Greek art. As time passed, Roman homes as well came to contain frescoes and moveable paintings.

By the time of the Renaissance, traders and explorers provided Europeans with biological specimens and cultural artifacts from around the world. The wealthy class began to collect these objects in cabinets, drawers, and even entire rooms dedicated to flora, fauna, and cultural curiosities. These Wunderkammer, or cabinets of curiosity, are often cited as the first “real” museums because

they attempted to organize knowledge, as represented by biological specimens and material culture, within architectural space. In 1682, Elias Ashmole donated his collection to Oxford University to found the Ashmolean Museum; in 1686, he codified the museum's structures in a memo on the museum's income, governance, and operations. This museum was one of the first to be open to the public.^[5]

While European museums came out of a tradition of aristocracy and the practices of elite travelers, collectors, and patrons, American museums arose out of different impulses. From their earliest days, American museums have been more entrepreneurial in that they tend to articulate their usefulness to society in terms of value to individuals and to communities.^[6] Throughout the nineteenth century, American museums were concerned with uplifting the masses and, in particular, assimilating new immigrants through the twin processes of education and enculturation. Free lectures and increased access to works of art, scientific specimens, and displays of new technology were meant to showcase American ingenuity and improve Americans' cultural and scientific literacy.

As the nineteenth century progressed, museums collected not only the best artistic production and most interesting scientific specimens of their own region, but from their nation's colonial territories as well. In the twentieth century, foreign governments and indigenous peoples raised questions about the ethics and legality of the acquisition of this cultural patrimony. In response, museums in the developed world continue to rethink how they represent "others" within their galleries and halls, while many museums in the developing, formerly colonized, world attempt to divorce themselves from the colonial heritage at the core of their museums' missions and collections.

In the twentieth century, many museums increased their focus on public education, particularly on the education of children. Museums targeting young visitors emphasized hands-on activities, role-playing, and kinesthetic exercises that engage the whole body. Families thus became a core constituency of the museum-going public, and museums extended their outreach to families and neighborhood groups, thereby building the institutions' sensitivity to the interests and needs of local and regional inhabitants.

FUNCTIONS

In the edition of the *Encyclopedia of Library and Information Science* published in 1968, James L. Swauger named three basic functions of museums: collection, study, and communication.^[7] Twenty-first century museums have embraced a much broader, and at the same time very granular, spectrum of functions. Collecting remains at the core of many museums' missions, and the study of these collections—whether they may be centuries-old textiles, natural history museum specimens, or oil paintings—by

scholars is still an important function of museums that own art and artifacts. Today, however, museums function just as much as institutions of public education, civic outreach, and leisure or "edutainment."

Collections and Research

Historical museums, art museums, and natural history museums have at their core a collection of objects—artifacts, fine arts or crafts, or scientific specimens. Museums place these objects on permanent or temporary exhibit, but in museums with larger collections, an object may never go on display. For example, the Smithsonian Institution in Washington, D.C., has more than 138 million objects in its possession; even within its 19 museums, 194 affiliate museums, and 9 research centers, it would be impossible to exhibit all of those objects in any human lifetime.^[8]

Museums acquire objects in numerous ways. Scientists and anthropologists collect specimens and artifacts in the field, in the best cases adhering to local and international ethical guidelines regarding the acquisition of objects. Individual collectors give objects to museums during their lifetimes or bequeath them to the institution upon their death. Museums also purchase art, artifacts, and other objects, or trade with other museums to secure these objects for their collections. Zoos, aquaria, and gardens additionally have breeding and cultivation programs that increase their collections.

Museum collections can be contentious. Stakeholders and members of the public have called into question museums' ownership of sacred tribal objects, human remains, and ancient art. In the United States, this critique resulted in the 1990 North American Graves Protection and Repatriation Act (NAGPRA), which requires any institution receiving federal funding to return to the original tribes sacred objects, human remains, funerary artifacts, and related objects.^[9] Internationally, agreements among countries and museums have made institutions more responsible for determining the provenance of objects in the hopes of reducing the traffic, for example, of archaeological artifacts and early art from their countries of origin. Most notable among these agreements may be the 1970 United Nations Educational, Scientific and Cultural Organization (UNESCO) Convention, which regulated the traffic of cultural artifacts, and particularly antiquities, from one country to another.^[10]

Most museums allow researchers access to objects not currently on display. Many collections are open to the public by appointment, but some institutions restrict access to fragile or otherwise sensitive collections to scholars who provide relevant credentials. Curators and archivists at these museums frequently provide finding aids online, as well as guidelines on how to handle and photograph (or not) specimens, artifacts, and ephemera in the collections.

Increasingly, museums with collections are digitizing their texts and placing photos of their artifacts online as well. Many art museums let website visitors create “collections” of their favorite pieces of art. One museum that has made its digital collections particularly accessible is the Powerhouse Museum in Sydney, Australia, which has harnessed visitors’ interest in its collections to expand the museum’s understanding of both its objects and its visitors. The Powerhouse collections’ online interface allows visitors to “tag” objects with vernacular words and phrases, adding to its curatorial taxonomy of the museum’s objects a vernacular “folksonomy.”^[11]

Exhibits and Education

Museums are best known for their exhibitions. Exhibitions largely take two forms. The first type displays artifacts from a museum’s—or several museums’—collections, with the goal of giving visitors a comprehensive overview of, for example, an artist’s work, military aircraft, or animals of the Pleistocene. The second type of exhibit—which has come to dominate larger museums’ exhibition design—is less focused around objects, but is fabricated to provide a particular learning experience. For example, an exhibit on climate change may not lend itself to the exhibition of artifacts; in this case, an exhibition designer would create interactive exhibits that are less dependent on artifacts and more focused on informational panels, multimedia presentations, and hands-on activities designed to facilitate learning about the phenomenon.

As increasing numbers of cultural organizations compete for the same pool of funding, many of the larger museums have turned to “blockbuster” exhibitions. Examples of this type of exhibition include King Tut and the Golden Age of the Pharaohs by National Geographic and the Supreme Council of Antiquities of Egypt, The Vatican Collections—The Papacy and Art and Van Gogh in Arles.^[12] These exhibitions are so popular that visitors must reserve tickets in advance and enter the museum at a specific time. These exhibitions have been criticized for needlessly endangering works of art by shipping them around the world, for shifting the focus of museums from curatorial scholarship to marketing and visitor numbers, and for driving traffic from smaller museums toward those that can afford to mount these expensive exhibitions.^[13] Supporters of blockbuster exhibitions claim they bring new audiences and revenues to museums, as well as make world-famous art and artifacts more accessible to the public.

Not all exhibitions are curated by experts. Community curation, or the selection and interpretation of objects by museum outsiders, takes many forms. In 1991, the Walsall Museum in the United Kingdom invited townspeople to nominate their own collections for display at the museum. This “People’s Show” became so popular that it was repeated in later years at Walsall and elsewhere.^[14]

In 2007, the Tech Museum of Innovation in San Jose, CA, invited inhabitants of the virtual world Second Life to prototype exhibits in the virtual world; several of these prototypes were fabricated and exhibited in the real-world Tech Museum.^[15]

Some curators are skeptical of crowdsourcing, but others see an opportunity for museums to curate the endless digital stream of user-generated content. In the analog world, museums have long filled this role of identifying information and items relevant to their communities and organizing content for visitors.^[16] Thanks to interactive digital displays—multitouch tables are but one example of this technology—museums’ curation of this content need not be limited to their websites; curators and educators can literally place the information at users’ fingertips on the exhibition floor. Some of these exhibitions sit at the nexus of libraries and museums. For example, the Emerging Issues Commons is a physical gallery in the Hunt Library of North Carolina State University’s Centennial Campus in Raleigh. Using multitouch tables and walls, visitors can interact with dynamic, data-driven graphics, watch historical and contemporary videos showcasing how the public has addressed the state’s problems, view relevant social media streams, learn how state government policies come into being, and recommend solutions to current and emerging challenges. The gallery has a companion website where visitors may continue their engagement at home.^[17]

Museums use their websites to expand their audience beyond visitors to their physical sites. News of events, exhibition previews, and even searchable collections all have proven to be of interest to web visitors. Individuals and organizations that lack the resources or interest to host visitors in a physical space are increasingly creating online “museums.” The best resource to date on these online museums is the Museum of Online Museums (MoOM), which includes links not only to revered institutions such as the National Portrait Gallery and the United States Holocaust Memorial Museum, both of which are in Washington, D.C., but also to such virtual exhibits as a locomotive horn sound file collection, the Museum of Soviet Uniform Caps, and the Gallery of Firework Label Art.^[18]

Leisure Destination

Individuals and families turn to museums not just for learning experiences, but as leisure destinations. Over the past several decades, museums have struggled to balance their appeal as leisure destinations with their educational missions, and family groups are at the center of this tension. Although families may come to museums to help their children learn, the visit is as much about forging family and individual identity as it is about the exhibition’s content. In fact, recent visitor studies have analyzed not only what individual visitors perceive in exhibits, but also what they say to one another in family groups.

This research also takes into account the fact that any given museum is but one island in an archipelago of a family's learning resources.^[19] Families are looking for time and space to spend together in an era where family time is less plentiful and childhood is compressed.^[20]

Museums and similar sites are not stand-alone institutions, but part of a leisure landscape. For example, Carole Blair and Neil Michel have demonstrated that the Astronauts Memorial at the Kennedy Space Center Visitor Center in Orlando, FL, is part of the same cultural landscape as Disneyworld.^[21] Similarly, the Smithsonian Institution museums are part of a larger touristic experience in Washington, D.C. Accordingly, a museum's education and marketing teams need to think beyond the walls of their institution when planning for visitors.

Civic Outreach

Traditionally, a museum's functions have been dictated by the type of museum it is (e.g., art museum, children's museum), but in recent years more museums have been crossing over into other areas of inquiry and expanding their public service missions. Museums are motivated to make this shift as they reevaluate their missions in light of changing patterns of public life and civic participation online and offline. Part of this effort has been providing free or inexpensive space for people to interact informally in public.^[22]

These museum programs are diverse and frequently focus on children and youth—but without the feel of a more traditional museum education program. For example, the Boston Children's Museum in Massachusetts has entered into numerous collaborations with other institutions in the city, developing community open spaces within several office complexes near the museum.^[23] The de Young fine arts museum in San Francisco engages high school students as “museum ambassadors” who lead interactive activities at classrooms and community centers and offer tours at the museum.^[24] The National Museum of American Jewish History in Philadelphia, PA, formed a neighborhood action bureau that trained high school students to interview longtime residents about race relations and other neighborhood issues, particularly relations between Jewish Americans and African Americans.^[25]

In Africa, where many museums have sought to divorce themselves from their colonialist roots, museums are focusing on community service, particularly in urban areas that have been stressed by immigration from rural regions. The Musée des Civilisations in Abidjan, Côte d'Ivoire, participated in the project “African Ingenuity: Creative Recovery and Recycling.” The museum produced an exhibit of recycled and repurposed objects and drew attention to living conditions and caste systems within major African cities.^[26] Other museums in Africa, including the National Museum of Nigeria, are moving from a mission of merely collection, preservation, and

exhibition to a more proactive role in fostering healthy urban development, for example by opening up, via exhibitions, conversations about traffic jams, the relative safety of the suburbs over the cities, or mosquito eradication efforts.^[27]

Museums and related institutions around the world have recently invested considerable resources in explaining climate change and encouraging visitors to consider ways to address this global crisis. Sometimes the engagement is very subtle, for example in the British Museum's gigapixel exhibit *Stories in the Rock*, which uses exceptionally large-format photographs of petroglyphs in part to tell an older climate-change story of the desertification of the Arabian Peninsula.^[28] In other cases, institutions tackle climate change head-on. In 2015, The Long Beach Aquarium of the Pacific in Southern California, for example, convened a climate change summit that brought together policymakers; scientists from the government, university, and nonprofit sectors; industry representatives; and members of the public to identify critical areas of research that might provide solutions to Southern California's vulnerability to rising temperatures, drought, and coastal flooding.^[29] Some scholars and museum professionals have recently called for using the accelerating climate change crisis as an opportunity to shift museums' approaches to preservation. Rather than addressing heritage—and particularly historic sites and other significant places in a community—as something that can be preserved perpetually, cultural institutions should, they argue, help visitors and the wider community adapt to new realities and to heritage loss.^[30]

TYPES OF MUSEUMS

Museums come in many forms, including those listed as discussed the following list. Due to budget constraints, new technologies, patron or community interests, and changes in staff, museums are always innovating and partnering with other organizations, forging new kinds of institutions. This list, therefore, is by no means exhaustive.

Art museums: Art museums collect, exhibit, and conserve arts and fine crafts. Unlike natural history museums and science centers, which have wide appeal, especially among families, art museums have long battled with a public perception that they are elitist institutions. Indeed, the spare white, hushed galleries dotted with security guards, coupled with abstract artworks that may feel emotionally or intellectually inaccessible to laypeople—these may decrease enthusiasm for an institution significantly. However, like most other museums, art museums have been undergoing a transformation to make themselves more appealing to families and laypeople. For example, the Louvre in Paris has programs specifically targeting families, as well as workshops for children age 4 and older.^[31] The Museum of Modern Art in New York City

offers “Tours for Fours” and “Tours for Tweens” to satisfy young visitors, as well as family art workshops and films.^[32]

Natural history museums: Traditionally, natural history museums’ exhibitions housed hundreds, if not thousands, of preserved specimens of plants and animals (e.g., taxidermied mounts or skeletons). In the late nineteenth and early twentieth centuries, glass cases of specimens gave way to habitat group dioramas that placed animals in context but in many cases were loaded with cultural messages about nuclear families and patriarchy.^[33] These aging dioramas, which were expensive to install and are not simple to renovate, are gradually being replaced by more interactive, multimedia exhibits and, in some cases, even older approaches to natural history display. For example, the renovated mammal hall that opened in 2003 at the Smithsonian’s National Museum of Natural History features single, magnificent taxidermied mammals—a more “big game” approach to display—in lieu of habitat groups. Through video screens on walls and floor, shifting lights, and targeted sounds, visitors to the exhibition experience changing weather patterns on the veldt and in the forest. Natural history museums are also increasingly targeted at laypeople; instead of having rows of dioramas or specimens labeled with species’ common and scientific names and a bit of explanatory text, exhibits are themed and narrative. The Smithsonian mammal hall, for example, welcomes visitors to a “Mammal Family Reunion.”^[34]

Science centers: Science centers (sometimes called science and technology centers) take a decidedly less object-oriented approach to museum exhibition in that most science centers do not have collections in the sense that other museums do. Science centers are intensively hands-on, informal learning environments that encourage observation, curiosity, role-playing, cooperation, and a sense of discovery.^[35] Like children’s museums, science centers are audience-focused rather than exhibits-centered (and by extension, curator-centered). The Exploratorium, which was founded in San Francisco in 1969 by noted physicist Frank Oppenheimer, is often credited with being the first science center.^[36]

Children’s museums: Children’s museums seek to provide an enriching experience for young visitors, particularly those in their communities. The first children’s museum, the Brooklyn Children’s Museum in New York, was founded in 1899; today there are 300 children’s museums worldwide. Like science centers, children’s museums emphasize hands-on learning, discovery, and play. Also like science centers, they tend not to have large collections, although the Brooklyn Children’s Museum has 29,000 natural history specimens and cultural artifacts.^[37]

Museums of history or anthropology: History museums collect artifacts and ephemera related to the specific region or era reflected in the museum’s mission. Very

large museums, such as the National Museum of American History in Washington, D.C., have the space and staff resources to collect a wide range of artifacts from all eras of American history. Other museums, such as the Computer History Museum in Mountain View, California, focus their collections and exhibitions around more specific objects. These museums’ exhibitions might be celebratory, informative, or commemorative. One particularly interesting approach to history is embodied by the Jim Crow Museum of Racist Memorabilia at Michigan’s Ferris State University, which collects and exhibits objects—contemporary and historical—that draw on racist stereotypes of African Americans. The museum not only documents a history of hate but also serves as a resource for civil rights organizations.^[38]

Living history museums: At these sites, historical reenactors wear the clothes and perform the tasks of people living in an earlier era. At some sites, these reenactors may serve as docents, who explain what they are doing and its significance to visitors, and even give visitors an opportunity to try a task or chore. The Living History Farms in Iowa are an example of such a site. At other living history museums, the reenactors are historian actors who never break from character. Some sites blend these two approaches. For example, at Plimoth Plantation in Massachusetts, Native American staff at the Wampanoag Homesite dress in Native historical garb but serve as interpreters rather than actors in order to better inform visitors about Native American culture today and in the past. Yet in the English Village portion of Plimoth Plantation, interpreters portray the daily life and special events experienced by specific settlers in 1627.^[39]

Historic house museums: Historic house museums concern themselves with the conservation, maintenance, and interpretation of homes—and often their accompanying landscapes—of historic significance. The exhibition and education programs of these museums usually focus on the everyday lives of the former inhabitants of the house.^[40] The notable exceptions to this practice are U.S. plantation house museums, 80% of which, according to one survey, either do not mention the contributions of slaves or trivialize their presence at the site.^[41]

Community-based museums: Community-based museums take many forms, but all insist on representing and serving the people in their communities. “Community” can be defined narrowly, to include a museum’s immediate community, or more broadly, to encompass a regional or ethnic mission. For example, the Smithsonian’s Anacostia Community Museum sits in a largely African-American community in Washington, D.C., but focuses on African-American history and culture as well as its community’s history.^[42] In its exhibitions on art, history, the environment, and people, the Oakland Museum of California aims to be responsive to its immediate community.^[43] Community museums are among those most likely to partner with other cultural

organizations and institutions; take, for example, the Heart of Brooklyn cultural partnership among the Brooklyn Museum, Brooklyn Public Library, Brooklyn Botanic Garden, Prospect Park, Prospect Park Zoo, and the Brooklyn Children's Museum to promote learning and access to collections.^[44]

Indigenous museums: In the United States and elsewhere, European immigrants and others long have been fascinated with the culture of the land's indigenous peoples. Individual and institutional collectors amassed—through means ethical and unethical—vast collections of native art and material culture. Museums used these artifacts—some of them sacred objects that native peoples felt should not be put on display—to represent indigenous cultures in ways that were not always accurate and in many cases were racist. With the rise of native self-determination movements in the 1960s and 1970s, indigenous peoples increasingly sought to represent themselves in museums.^[45] The result has been the establishment of museums that either were established by native peoples or in partnership with them. The largest example of this in the United States is the National Museum of the American Indian in Washington, D.C. In Australia, the Aboriginal Heritage Unit works with native communities to establish cultural centers to represent their cultural heritage and “keeping places” to safely and securely house artifacts.^[46]

Planetaria: A planetarium is a large theater designed for educational and entertaining presentations about objects in the solar system, Milky Way galaxy, and the larger universe. Usually these theaters have a dome-shaped ceiling and walls, as well as seats that recline backward so that audiences can comfortably look upward to see stars projected onto the dome. Planetarium shows may mimic space flight, instilling in viewers a sense of the universe's scale and the relative size and distance of night sky objects. The original planetarium shows used optical “star ball” projectors that simulated the movements of planets and stars relative to Earth. Contemporary planetarium shows tend to use digital projectors that allow for virtual travel into the night sky.^[47]

Botanical gardens and arboreta: Botanical gardens and arboreta showcase plants and trees. These gardens not only serve as respites from urban or suburban landscapes but also conserve local, native, or endangered plants. Increasingly, these gardens target multiple users: runners, teachers and students, families with small children, the elderly, artists, and research scientists. For example, the Huntington Botanical Gardens in San Marino, CA, features a children's garden with hardy plants, low tunnels overgrown with vines, and fountains at toddler height.^[48]

Aquaria and zoos: Aquaria and zoos display and conserve animals that live in freshwater and saltwater and on land. Although long criticized by animal activists and others for keeping animals in restricted spaces and barren environments, many zoos and aquaria have sought to replicate animals' habitats in order to foster breeding and

conservation. Of particular current interest is amphibian conservation because large numbers of frogs and other amphibians are threatened with extinction due to habitat loss and a highly infectious disease. Other high-priority conservation projects include ocean habitats and elephants.^[49]

OPPORTUNITIES

Technology

Museums are increasingly embracing the opportunities of the digital, networked age. Many museums have gone beyond websites that provide information, choosing instead to offer online visitors an interactive virtual experience—and in some cases, let visitors contribute to the site's content. Visitors comment on museums' blogs and Facebook pages, contribute videos of their museum experiences, enter videos they made into museum-sponsored contests, tag items in museum collections in crowdsourced projects, and share photos on Instagram and Flickr.

Many museums have smartphone apps that allow visitors to engage more deeply with exhibition content. In late 2015, the Brooklyn Museum released ASK Brooklyn Museum, an app that lets visitors ask real-time questions of art historians and educators who use Bluetooth-aware sensors to determine next to which works visitors are standing at the moment they use the app.^[50] Monticello, Thomas Jefferson's former estate, developed an app in 2014 that shares haunting details about the slaves who lived and died there.^[51] A coalition of museums in the United Arab Emirates share an app, MuseumsUAE, that provides visitors with information about each museum, including which museums are closest to them. In addition, as visitors check in at each museum, the app awards virtual badges that reveal additional information about each museum.^[52]

A slightly older yet still compelling use of digital technology is the United States Holocaust Memorial Museum's Mapping Initiative, which uses Google Earth to map and interpret sites of historical and 21st-century genocide. Google Earth users can explore burned-out villages in Darfur and view accompanying texts and photographs documenting the destruction and loss of human life. The museum has similarly mapped the Holocaust, providing photographs, texts, and animated maps that demonstrate the scope of Nazi crimes against humanity.^[53]

Civic Discourse

As explained earlier in this entry (see section “Civic Outreach”), museums are already reaching out to their communities in various ways. In an age of reduced funding for public education, large-scale human suffering, and local

and global environmental crises, many museums and similar cultural and scientific institutions are redoubling their outreach efforts. These new activities go beyond bringing objects and lessons to school classrooms or setting up temporary exhibits in public venues. Increasingly, museums see themselves not merely as institutions that perform civic outreach, but as institutions that facilitate civic discourse.^[54]

As part of this effort, some museums have teamed with universities and scientific organizations to promote efforts, such as *Café Scientifique*, where scientists and laypeople gather informally to discuss current issues in science. *Cafés Scientifiques* meet in locations around the world, including—to name just a few—Uganda, Iran, Israel, Bulgaria, Finland, Mexico, Chile, and the Philippines.^[55] These and other efforts at promoting civic discourse—symposia, forums, and more—challenge traditional notions of the museum as a single site where people walk quietly through large halls, gazing at or interacting with objects. Some museum professionals find this shift disconcerting and not entirely within the missions of their museums, but others feel museums must be more proactive in leading and facilitating discussions and conversations lest museums become irrelevant in the larger everyday culture.

CHALLENGES

Politics

Museums the world over feel pressure to modify their exhibition content as a result of broader cultural and political landscapes. One particularly stunning—and oft-cited—example of this pressure resulted in the Smithsonian's National Air and Space Museum cutting back significantly on a 1995 exhibit commemorating the dropping of the atomic bombs on Hiroshima and Nagasaki. Complaints from veterans and conservative political groups convinced the museum to change the exhibition from one that looked at the decision to drop the bomb, the bombing itself, and its aftermath to a much smaller one centered around the restored fuselage of the *Enola Gay*, the plane that dropped the bomb.^[56]

Criticism of this exhibition and others has led the public, politicians, and museum professionals to ask what exactly is the purpose of a museum, and particularly of a history museum. When it comes to interpreting events such as the bombing of Japan, what is the proper role of a museum, especially if it receives state or federal funding? Should the museum commemorate the bombing with displays of artifacts accompanied by simple, factual labels (even though these facts will likely be contentious); celebrate the contributions of the innovators and soldiers who brought about the end of the war in the Pacific; or look more critically at the bombing based on what we have learned, for example, about radiation during the past half

century? Should museums be places where people's beliefs are challenged, where people are asked to think critically about commonly held notions about science and culture? Or should museums be a place where a culture's beliefs and knowledge are showcased uncritically? These are questions that are far from settled within communities and cultures around the globe, but professionals in museum fields tend to see museums as institutions of education that on occasion challenge visitors' understanding of the world and their places in it.

Contemporary transnational politics and events also affect museums in the short- and long-term. In the second decade of the twenty-first century, the rise of the self-styled "Islamic State" (ISIS) operating in Syria and Iraq not only touched off a human rights and refugee crisis of tremendous proportions; it also threatened the ancient cultural patrimony of the region. Jihadist fighters blew up signature historic sites in Palmyra, Syria, and the Islamic State funds its terror in part by selling antiquities on the black market.^[57] Prior to the rise of ISIS, the Taliban and Al Qaeda looted museums, destroyed antiquities, and obliterated historic sites, including the famous 150 ft tall Bamiyan Buddhas carved into a cliff in central Afghanistan.^[58] As a result, in some parts of the world, the physical security of museums and historic sites has taken on new urgency and importance.

Funding

Securing adequate money to maintain their collections and exhibits, as well as fund their education and outreach efforts, has been a perennial problem for many, if not most, museums. Museums typically rely on financial support from a combination of government agencies, foundations, and private fundraising. In the United States, funding for educational institutions shifts depending on which political party is in power in Washington, D.C., and even when funds are available, often those projects that favor the dominant political party's ideology receive funding over those that present alternative views.

To keep their doors open, most museums charge admission fees. It can be difficult to strike a balance between the amount of money a museum needs to collect and what the average visitor—and particularly the average family—is willing to pay. The result is typically a modest admission fee, although some museums charge no admission. For example, the Smithsonian Institution offers free admission to all its museums, and the United Kingdom features more than 50 free national museums.^[59] In January 2009, French President Nicolas Sarkozy announced that French citizens aged 18–26 would gain free admission to public museums and monuments, including the Louvre—which set off its own controversy because non-French residents of France saw this policy as discriminatory.^[60] Other museums raised their admission fees considerably in the 2000s. In 2004 the Museum of Modern Art in New York

City reopened with a new building and a \$20 fee for adult visitors, representing a 60% increase in ticket prices, and in 2008 the California Academy of Sciences in San Francisco also opened a new facility with a \$24.95 admission fee for adults, a significant increase over its previous ticket price of \$10.^[61] By late 2015, the Academy's price had risen to \$34.95 for adults and \$29.95 for youth.^[62]

Coupled with stiff competition for private grants and government funding, museums' modest revenue means museum professionals, like many who work in the non-profit sector, tend to receive salaries far below those of professionals in the corporate sector. While many people enjoy long careers in the museum field, lower paid positions experience a good deal of turnover as younger employees realize they might not be able to balance their personal budgets on such incomes. Those who remain in the field alternately describe it as enriching and frustrating; they have big ideas and ideals, but they may lack funding and public support for their projects.

PROFESSIONALIZATION AND TRAINING

The museum field boasts countless areas of specialization, but among them are curating, education, exhibit development, conservation, historic preservation, organizational management, development (fundraising), evaluation, and marketing and public relations. Depending on the size and status of the museum, some of these career tracks begin with entry-level jobs that require little prior experience or training. Others, such as curation or conservation, typically require advanced degrees in relevant disciplines. Museum professionals have advanced degrees in fields as diverse as museum studies, art history, library science, education, integrated pest management, conservation, and nonprofit management.

Undergraduate programs in museum studies are relatively rare; graduate degree and certificate programs are far more common. The best museum studies programs provide their students with a historical perspective on museums, a solid theoretical grounding in areas of interest to the student (e.g., education, curation, marketing), and access to internships at the best regional and national institutions. The Smithsonian Institution keeps an updated list of museum studies programs internationally.^[63]

CONCLUSION

Museums are dynamic institutions. While conservative curators, researchers, and some patrons might see collections and their exhibition as museums' *raison d'être*, the museum-going public, museum educators, and others continue to make museums more responsive to community needs and thus more relevant to people's everyday lives. "Collaboration," "public outreach," and "civic discourse"

are key terms in this new paradigm—one that undoubtedly will persist in this highly networked, digital age.

Museums and Community

Tamara Biggs

Chicago History Museum, Chicago, Illinois, U.S.A.

Abstract

In spite of Charles Willson Peale's ideal of a democratic museum, most in the early nineteenth century were either eclectic and intimidating, or filled with sham amusements. In the late nineteenth and early twentieth centuries, museums began to consider their educational mission on an equal par with collecting and research. A lack of representation in mainstream museums led to the foundation of many American and international ethnic museums, beginning with African American museums in the 1960s, giving voice to cultures often excluded from the historical narrative. Larger institutions responded to societal demand for inclusion by engaging community advisory boards and first voice perspective through oral history. The most recent museum community to develop has been online, and crosses traditional barriers of race, class, and gender. Innovative museums looking to the future have invited visitors to participate in the narrative process.

INTRODUCTION

The ever-changing relationship between museums and their communities is a topic which reflects the fluid landscapes of culture and technology. The industry which began as a smattering of avid scholars amassing personal collections has grown through the efforts of individuals and organizations to become a global network of public resources. Presentation and accessibility have improved to attract a wider demographic, and in the past 50 years a staggering array of cultures and viewpoints has come into the public eye through the establishment of ethnic and neighborhood museums. The relationship between community and museum has been personalized through the collection of firsthand accounts and the involvement of community advisory groups, while information is becoming ever more accessible through the reaches of the Internet. The predominant trend in the history of the relationship between museums and their communities is a steady increase in the appeal and availability of information to all facets of the population.

BODY OF TEXT

Early American Museums

The founder of the first American museum, Charles Willson Peale, struggled with some of the same issues as museums of the twenty-first century. Namely, how does one endeavor to attract, educate, and entertain the broadest possible audience while maintaining a commitment to research and scholarship? Peale believed that government financial support would make both of these ideals possible. In an address to the state legislature of Pennsylvania,

printed in *Poulson's American Daily Advertiser*, December 18, 1810, Peale said

In Europe, all men of information prize a well regulated museum, as a necessary appendage to government, but in several parts of that quarter of the earth, the means of visiting those repositories, are within the reach of particular classes of society only, or open on such terms or at such portions of time, as effectually to debar the mass of society, from participating in the improvement, and the pleasure resulting from a careful visitation.^[1]

Peale solicited the new American government to provide public monies so that he could operate a museum that would offer "rational amusement" to a wider swath of society; he articulated a more democratic intent than the models in Europe. Believing that natural history could "promote National and Individual happiness,"^[2] he experimented with presentation techniques, using his fine artistic skills to paint backdrops for mounted specimens. At the end of the gallery, he even included a three-dimensional natural setting, with trees, shrubs, and a pond, for a collection of mammals, reptiles, amphibians, and birds. But he could neither gain public funding nor attract enough visitors to pay the 25¢ admission fee to keep the doors open. The Philadelphia Peale Museum closed in 1827 shortly after his death, and the collection was largely sold off to P. T. Barnum and Moses Kimball.

Two of Peale's sons, Rembrandt and Rubens, also tried their hands at museums, opening one in Baltimore, and later one in New York. Rubens had an especial flare for marketing: he installed gas lighting to attract visitors at night, and he hosted (for the substantial fee of \$650) the blockbuster of the day—the first Egyptian mummy brought to America. The effectiveness of such entertainment events is recorded in his detailed accounts. For

example, visitorship spiked during the Mummy's six weeks of display, and generated \$1842 of income.^[3]

Like the Peale family's, many early American museums actively appealed to public interests in an effort to increase visitation. In their endeavors to remain solvent, they struggled with the tension between entertainment and education, often including such elements as wax figures and vaudeville-like performances. P. T. Barnum had no qualms about promoting amusement and hokum before science in his New York Museum, to the extent that when the museum burned in 1870, he abandoned the museum business and devoted his attention to the circus.

On the other hand, early private collectors, more concerned with their own education than that of the public, joined to form societies and share information.

The naturalists who studied and collected natural history objects typically shared a commitment to self-improvement, group collaboration and national advancement. They created local societies to link the layers of individual activity—private conversations, semi-private correspondence, exchange of specimens, and presentation of ideas—into a collaborative project to identify and map all species in the American landscape.^[4]

While the public may have been allowed into the sanctums of these societies, they found no aids to help them understand what they saw. There were few docents or legible labels, and the species were organized for efficient storage, not pleasurable viewing. Indeed, the societies became just one more way to establish the elite standing of well-heeled Americans. Museum theorist Stephen E. Weil put it this way: "Museums were created and maintained by the high for the low, by the couth for the uncouth, by the washed for the unwashed, by those who knew for those who didn't but needed to know and who would come to learn."^[5] Neither the P. T. Barnum types nor the natural history societies democratized the natural sciences as Peale had yearned to do.

Birth of Museum Education

Beginning in the 1870s, Alpheus Hyatt at the Boston Society of Natural History, aided by teacher Lucretia Crocker, worked to attract a more general public. They hired guides, "introduced special evening and Saturday classes, produced guidebooks, and added more descriptive charts and posters to displays. . . ."^[6] After the Civil War, systematic displays (with rows of species organized by their biological relationship to one another) became the norm for "serious museums." But teachers and the general public exerted their influence to produce more attractive and understandable displays. George Brown Goode, the Smithsonian Institution's Associate Director, said in the SI's first circular, that the museum had three roles: museum of record, museum of research and museum of

education. In other words, the Smithsonian established public education on equal footing with collecting and research.

Into this milieu came John Cotton Dana. Primarily a librarian, he first revolutionized that field in Denver, where he headed the Denver Public Library from 1889 to 1898. He believed that libraries', and later museums', prime mission is relevance and usefulness. He was instrumental in changing the library from "a closed temple of 'wisdom undisturbed' to an open workshop of delight and learning"^[7] by introducing open stacks, a special business library, a children's library, community rooms, branch libraries, and foreign language collections to serve immigrant populations. When he relocated to Newark, New Jersey to become head of the Free Public Library in 1902, he also took on the task of developing a museum using the same principles of usefulness to the public. Noting that the citizens of Newark had access to landmark temples of art and natural history across the river in New York City, he concluded that what was needed was a museum of, by and for Newark—a museum that was "supported by, and. . . duty bound, to try to be of direct value and service to a city of industries. . . for the pleasure and advantage of our chiefest patron—the people of Newark. . . ."^[8] Among the innovations there during his lifetime were hiring an educational advisor, making 300 trips to museums to learn what worked or didn't for others, holding public forums to gain insight into public desires, mounting a wide range of exhibitions (such as clay products of New Jersey with "the daily presence of a skilled potter," or immigrant textiles collected through schoolchildren), lending collections to classrooms, establishing one room as a children's museum, and forming a junior museum club.

Dana spread his revolutionary ideas through letters to *The New York Times*, a series of small volumes under the general title "The New Museum," papers at the annual meeting of the American Association of Museums (founded in 1906), and finally by the founding one of the nation's first museum studies programs at the Newark Museum in 1925.^[9] The New Museum continues his legacy through innovations such as the High School Art Program (HSAP), one of the first museum education programs in the country to engage at-risk teenagers in contemporary art, launched in 1980.

Ethnic Museums

The next sea change for museums and community came with the Civil Rights movement. While scholarship on the history of blacks was well developed by the early twentieth century, the dearth of African Americans in museum positions that could influence the interpretive course meant that mainstream museums continued to teach and display a distorted and biased version of America's past.

Consequently, in the 1960s and 1970s, blacks formed their own community-based museums to show that they indeed held an integral place in history: The DuSable Museum of African American History in Chicago, Illinois (1961); The Charles H. Wright Museum of African American History in Detroit, Michigan (1965); the African American Museum and Library at Oakland, California (1965); and the National Afro-American Museum and Cultural Center in Wilberforce, Ohio (1972). Most recently, Congress chartered the newest Smithsonian museum, the National Museum of African American History, in 2003. The NMAAH will allow African American scholars and educators a federally supported institution to preserve, study, and share their unique place in American history.

The establishment of Latino art and culture museums followed on the heels of the movement for African American Museums: El Museo del Barrio in New York City (1969); The Mexican Museum in San Francisco (1975); Chicago's Mexican Fine Arts Center Museum (now the National Museum of Mexican Art, 1982); the Mexic-Arte Museum in Austin, Texas (1983); and many others since then. Their shared first-voice identity "utilizes Latino self-expression as a lens for examining parallel experiences shared by many cultural communities..."^[10] Carlos Tortolero of Chicago's NMMA reiterates that the museum is an expression of the Mexican American community, but that it is a place for everyone. "We want both the local community and the mainstream world to visit. . .so that we can break down some of the barriers. . .If only our own people come here, we will have failed our mission."^[10]

Because The Native American Graves Protection and Repatriation Act (NAGPRA) of 1990 coincided with the licensing of many Indian casinos, American Indians had the legal means to reclaim many of their ancestors' remains and sacred artifacts from American museums at the same time that they were gaining the financial ability to house them properly. This convergence of circumstances has contributed to a renaissance on many reservations, and the establishment of approximately 300 tribal museums and cultural centers. The noteworthy Mashantucket Pequot Museum in Connecticut (1998) is a 308,000 square foot complex that cost \$193 million.

Dozens upon dozens of ethnic museums now operate in the United States, some of them arising early in the twentieth century, such as the Jewish Museum in New York in 1904, and Chicago's Polish Museum of America in 1935. The numbers, however, have burgeoned since the 1970s. These new ethnic museums range in size from small storefront operations run by volunteers to large initiatives such as the Japanese American National Museum in Los Angeles, California (1992); the Arab American National Museum in Detroit, Michigan (2005); and the newly expanded Wing Luke Asian Museum in Seattle, Washington (2008). The Chicago Cultural Alliance, formed in 2006, boasts a membership of 25 Chicago-area ethnic museums, historical societies, and cultural centers that

represent Cambodian, Swedish, Scottish, Irish, East African, African American, Mexican, Puerto Rican, Lithuanian, Latvian, Polish, Arab, Korean, Filipino, Japanese, Asian Indian, American Indian, Chinese, and Brazilian communities. Detroit's Cultural Exchange Network is a similar consortium of ethnic arts groups, and other cities have equally rich arrays of cultural assets. Immigrant populations may be Americanized, but they are not—indeed, they resist—becoming homogenized. Dr. Rosa Cabrera, senior urban anthropologist at the Field Museum in Chicago, asserts that these communities and their museums have a reciprocal benefit—that the very process of establishing a museum shapes community identity.^[11]

International Examples

The United States is not alone in the outgrowth of small neighborhood or ethnic museums. El Museo Shan-Dany was founded in 1986, through the cooperation of Mexico's Instituto Nacional de Antropología e Historia (INAH) and the community leaders of Santa Ana del Valle, Oaxaca. The project was inspired by the discovery of several archeological burial sites during plaza and road construction. INAH did not judge the artifacts to be of a high enough caliber for display in the national museum, but they were extremely important to the identity and patrimony of the people of Santa Ana. El Museo Shan-Dany became a model for the formation of 16 other museums in neighboring villages. Together they comprise The Union of Community Museums of Oaxaca, and like the Chicago Cultural Alliance, they do joint planning, fundraising, programming, and marketing.^[12]

The Lower East Side Tenement Museum, opened in 1988, does not focus on a particular ethnicity. Instead, its community is defined by the former residents of 97 Orchard Street, an estimated 7,000 people from more than 20 nations between 1863 and 1935, when landlords chose to evict rather than invest in meeting new building codes. The museum connects its historic stories to the plight of current immigrant communities, many of them toiling in sweatshops just as the residents of Orchard Street 100 years before them. According to founder Ruth Abram, "Behind every door is a family with a different religion, a different language, each special and unique. But in the hallways, stoops, and streets, all those people are together pursuing the American Dream. . ."^[13] Because its mission is to promote tolerance through the historical perspective, the museum's programs ask what policies and attitudes persist as obstacles to immigrant families today.

Like the Tenement Museum, the District Six Museum was formed to preserve a neighborhood consciousness. But District Six did not have a "time capsule" building to resuscitate. In fact, there was no neighborhood at all after the Apartheid government of South Africa declared in 1966 that it would be "white" and the homes and businesses of the multiethnic residents razed. Some 60,000

people were relocated, but they never stopped fighting to regain the right to return. In 1989, the Methodist Church, one of the few structures left standing, became the center for an outpouring of collective memory, inscribed by former residents on a huge floor map. The Museum served as a tool to preserve memory and fight to reclaim the neighborhood for the dispossessed, a battle won in 1998. The Museum continues to work with community memory in the renovated Methodist Church.^[14,15]

Te Papa Tongarewa, the National Museum of New Zealand opened in 1998, does not give voice to its native minority through a special museum. Rather, the government adopted the concept of unified collections and narratives developed via a bicultural partnership. Tangata Whenua (the Maori, those who belong to the land by right of first discovery) and Tangata Tiriti (the Europeans, those who belong to the land by right of the Treaty of Waitangi) worked together to interpret the cultural heritage and environment of New Zealand, drawing equally on Maori and western knowledge systems. Te Papa's marae, or Maori meeting house, symbolizes this collaborative and consensual effort. A marae is a sacred place inhabited by ancestors; indeed the house IS the ancestor. Rigid protocols protect both the marae's power and the well-being of those who enter. The museum created a marae that gives all people the right to enter because of their shared history.^[16,17]

In 1999, the Tenement Museum, together with the District Six Museum (South Africa); the Gulag Museum (Russia); the Liberation War Museum (Bangladesh); Maison des Esclaves (Senegal); National Park Service (U.S.A.); Memoria Abierta (Argentina); Terezin Memorial (Czech Republic); and the Workhouse (United Kingdom) founded the International Coalition of Historic Site Museums of Conscience (now known as the International Coalition of Sites of Conscience) to unite institutions whose mission is to preserve difficult histories in order to enable an educated citizenry to build civil societies. The Coalition Web site states, "By initiating new conversations about contemporary issues through a historical lens, places of memory can become new centers for democracy in action. But the power of historic sites is not inherent; it must be harnessed as a self-conscious tactic in the service of human rights and civic engagement." Since its founding with the above 9 institutions, the Coalition had grown to 17 accredited sites in 2008. Regional Networks led by accredited members in Russia, Asia, Africa, and South America bring together an additional 20–30 organizations for joint projects, workshops, one-on-one consultations, and other activities to build the capacity of emerging initiatives and strengthen the collective memory. An Immigration Network of 1 European and 13 American members formed in 2008 to foster an international dialogue on current immigration issues. An additional 100 affiliate members around the world support the mission.^[18]

ICOM

The International Council of Museums (ICOM) is an older and larger organization founded in Paris in 1946 at the initiative of American Chauncey J. Hamlin, previously president of AAM and then president of the board of the Buffalo Society of Natural Science. The organization immediately established a cooperation agreement with United Nations Educational, Scientific and Cultural Organization (UNESCO), and within the first few years, 53 countries were active members. It has grown to currently boast 26,000 members from 151 countries. ICOM's mission includes professional cooperation and exchange, advancement of professional standards and ethics, and interpretation and preservation of the world's natural and cultural heritage, both tangible and intangible. Since its inception, ICOM has been a valuable ally for local museums to protect and repatriate cultural assets, through such initiatives as standardizing the ethics of acquisition, "One Hundred Missing Objects" publications that fight illicit traffic of cultural property, and the International Committee of the Blue Shield that provides preservation aid in emergency situations. This concrete aid to keeping tangible culture in the hands of the community that created it is accompanied by theoretical assistance in democratizing museums. Conferences, workshops, and publications on such topics as "Local Museums and Cultural Development Outside Large Centres" (1954), "The Most Effective Means of Rendering Museums Accessible to Everyone" (1958), and "Museum as a Cultural Centre in the Development of the Community" (1960) were early innovations. The theme of the 1995 ICOM conference in Stavanger, Norway, was "Museums and Community." ICOM also invests in capacity building for community museums, most notably training staff at the Nubia Museum (1993–2001), and facilitating training in new technologies in museums in Caribbean countries (2001). Recently ICOM has turned its attention to sustainable cultural tourism, recommending that museums promote "participatory democracy by bringing together heritage resources and their neighbouring communities, stimulating community based development through heritage tourism that contributes to poverty alleviation without compromising the integrity of heritage resources."^[19]

AAM's Museums and Communities Initiative

Mainstream museums have become increasingly attuned to diversifying the communities they serve, reaching out through innovative program partnerships, target audience marketing, special exhibitions highlighting local ethnic communities, multilingual labels, accessible design, and other new methods of inclusive interpretation. These cultural accessibility issues were important enough that the American Association of Museums conceived the Museums and Communities Initiative in 1998. AAM

convened a national task force, held six community dialogues around the country through 2001, and passed a Museums and Community Resolution in 2002,^[20] urging all museums to be active and collaborative in their communities. In 2002, AAM published two volumes to assist museums in becoming more community minded: *Mastering Civic Engagement: A Challenge to Museums*, and *A Museums and Community Toolkit*. AAM also hosted seminars on building community connections in Los Angeles and Philadelphia in 2003, and Chicago and New Orleans in 2004. While the grant-funded initiative ended in 2007, AAM continues to encourage the work between museums and community. AAM members can access current information on its Web information center.^[21]

In 2007, AAM took its community focus abroad, converting its International Partnership Among Museums (IPAM) program into the Museums and Community Collaboration Abroad (MCCA). From its inception in 1980 through the end of the program in 2007, the IPAM program made possible over 245 museum exchanges that focused on administration, collections care, education, research, marketing, and design. MCCA programs emphasize exchange projects that go beyond the museums and into the communities. The first granting cycle included a project that partnered the tiny Black Pine Animal Park in Indiana, with only three paid staff, with the struggling Dushanbe Zoo in Tajikistan. The Black Pine Animal Park prospers because of its ability to mobilize volunteers and in-kind donations, and through AAM's MCCA they have embarked on a training program for Dushanbe to adapt the Black Pine model to the Tajik community.^[22]

The National Park Service

In 2001, the Advisory Board of the National Park System, chaired by renowned historian John Hope Franklin, issued a report entitled "Rethinking the National Parks for the 21st Century," in which they called on the agency to use the Parks not just for recreation, but as springboards for intellectual and cultural enrichment. They admonished that the Parks "must ensure that the American story is told faithfully, completely, and accurately. . . . Our nation's history is our civic glue." Said Franklin, "The places that commemorate sad history are not places in which we wallow, . . . but instead places in which we may be moved to a new resolve, to be better citizens. Explaining history from a variety of angles makes it not only more interesting, but also more true."^[23] Northeast Regional Director Marie Rust responded by holding a workshop focused on civic engagement and agency in New York in December 2001. The Civic Engagement Initiative

is the National Park Service's challenge to itself, to find new ways to revitalize its mission of preserving and

interpreting our nation's natural and cultural heritage. Forming meaningful partnerships with the very people most invested in the parks will instill in them a sense of ownership, and ensure the relevance of NPS resources and programs.^[24]

Oral History

Oral history is one way for mainstream museums to record the experiences and inner lives of those "... absent from the historical record—workers, dissenters, recent immigrants, ethnic minorities, and farmers. . . ."^[25] This valuable tool had its beginnings even before the early days of recording devices, when such projects as documenting the narratives of 2,300 former Slaves was conducted by Works Progress Administration journalists. Its use exploded in the 1960s and 1970s, and some believe it has yet to reach its full potential. Richard Rabinowitz, president of the American History Workshop, notes that oral history videos in exhibitions allow the visitor to experience a conversation with the subject, not a lecture from "a masked authority figure with a very remote kind of knowledge."^[26] A milestone for the Smithsonian Institution's National Museum of American History was the 1987 exhibition *A More Perfect Union: Japanese Americans and the U.S. Constitution*. As a lesson on the constitution, the NMAH decided to tell a story of its violation: the saga of 110,000 U.S. citizens of Japanese descent who were held in internment camps during World War II. Selma Thomas, the filmmaker on the project, reflects,

We wanted to create a document that was incontestable. . . . but the oral history also gives it a humanity that is often lacking in other kinds of documents. . . . You're asking a person to relive a painful moment and make it part of the public record. It's very invasive. But unless they do it, some part of the historical record is missing from the public forum.^[27]

Oral history projects have proven even more integral to community museums than to mainstream museums. The Alutiiq Museum in Kodiak, Alaska, makes its collection come alive by showing artifacts to elders and recording their explanations of use and meaning. Recordings are also a means to preserve the Alutiiq language, in danger of dying with so few living native speakers. While the Alutiiq Museum is focusing on oral history as a tool to preserve its culture, the Japanese American National Museum has reached out to multiple cultures to preserve the history of a neighborhood. In its 2002 exhibition, "Boyle Heights: The Power of Place," oral histories of Jewish, Japanese, Mexican, Italian, Armenian, Russian Molokan, and African American families, conducted by a team of scholars, volunteers, and university and high school students, revealed the evolution of the neighborhood, and how these ethnicities interrelated. According to

Associate Curator Sojin Kim, the teenagers actually collected some of the most interesting stories, because the older interviewees were more open to sharing their stories with the young people than with scholars.^[27] The Boyle Heights project achieved a more diverse visitorship for the museum, and fostered a sense of pride in the participants.

Community Advisory Groups

Mainstream museums often invite community advisors to shape their exhibition, collection, and educational programs. The Denver Museum of Nature and Science has enjoyed the benefit of a Native American Resource Group since the mid-1970s. From 2003 to 2005, the Chicago History Museum employed a 15-member Teen Council to develop a Web site, a program series, and an exhibition, and also to create content by collecting 100 oral histories of growing up in the city. The Royal British Columbia Museum in Victoria, B. C., Canada, not only worked with Nuu-cha-nulth tribal members on a 1999 exhibition about their artworks, but the Nuu-cha-nulth also served as paid “hosts” in the galleries. Nuu-cha-nulth youth came to a deeper knowledge of their own culture by explaining it to non-native visitors. In the 1980s, the Field Museum in Chicago established the Center for Cultural Understanding and Change to help the museum connect with and understand its contemporary urban community. It convened a forum entitled “Conversations on Pluralism and Identity in America” and in 1998 launched Cultural Connections, an annual series of six programs, each jointly presented by two Chicago area ethnic museums. One pitfall for museums that convene community advisory groups for special projects is that they often disband them when the project is complete. Relationships must be based on more than just the museum’s agenda. Says Claudine K. Brown of the Nathan Cummings Foundation, “Each partner should be in a better position for having participated in the process.”^[20]

Communities on the Net

New trends in museum communities include those growing through the Internet. As early as 1996, The Fine Arts Museum in San Francisco launched “The Thinker ImageBase” (<http://www.thinker.org>) with 80,000 images from its collection, stating “The collections belong to the people of the City and County of San Francisco” and that the museum’s mission was to be more a resource than a repository. By 2003, it was noted that many museums had more virtual visitors than real visitors.^[28] Online communities can convene people for activities, discussions, games, exhibitions, stories, research, collaboration, and much more. The Carnegie Science Center in Pittsburgh, Pennsylvania created the social networking site, Braincake, in 2006, as part of the Girls, Math and Science Partnership. Girls aged 11–17 years join this upbeat virtual

community, whose tag line is “Smart. Sweet,” to participate in programs, get homework help, find out about scholarship and career opportunities, and blog about science.^[29] In 2008, Tate Modern in London, England, opened the Great Tate Mod Blog, inviting Web visitors to help shape the development of their new wing by posting photographs and ideas of their favorite spaces on a “mood board.”^[30] Museums are also taking advantage of existing social networking and other Web 2.0 sites. For example, the Chicago History Museum joined the MySpace community in 2008, and its profile reads “female; 101 years old; mood: cultured; interests: hearing and telling stories.” At the time of this writing, most of her friends were other museums.^[31] In 2006, San Francisco, California’s Exploratorium mixed real and virtual world experiences by inviting avatars (a virtual representation of oneself) to gather in the museum’s Second Life amphitheater to view a live Webcast of the total solar eclipse in Turkey. Second Life is an enormous, multiuser, three-dimensional online virtual world that people visit through their avatars, and explore virtual environments built by other people’s avatars. The museum also hosts events and tests prototypes on “Exploratorium Island,” their corner of the Second Life world. A staff avatar can make a presentation and take questions from an international avatar audience.^[32]

The information superhighway may connect a museum with visitors from around the world or down the block, but access is not universal. Poverty keeps away both the real and the virtual visitor in what has come to be known as the “digital divide.” Even though the United States is among the most networked nations in the world, the 2000 U.S. Census reported that among children 3–17, 77% of white households and 72% of Asian households had computers with Internet access, while only 43% of African American children and 27% of Latino children had Internet at home.^[33] While the gap is certainly narrowing, pockets of isolation exist in both urban and, perhaps even more so, rural regions of the United States.

Visitor-Generated Content

The Tech Museum of Innovation in San Jose, California, brought the real and virtual worlds even closer when it launched The Tech Virtual Experiment. In early 2008, the museum posted an open call on Second Life for avatars, individually or in virtual collaborations, to develop and design museum exhibits. Of the 50 virtual exhibitions created by hundreds of avatars, seven were converted to the real world and installed in the Virtual Test Zone gallery in June 2008.^[34] This kind of visitor-generated content may be an increasing trend embraced by museum innovators, but many museums still fear dilution of their authority. In 2005, Marymount Manhattan College Art Professor, David Gilbert, turned the museum world on its ear with a guerilla audio tour project called Art Mobs. His students produced unauthorized audio guides to works in

New York's Museum of Modern Art (MoMA), that they offered to the general public via the Internet, at a time when museums were only beginning to ponder the possibilities of downloadable media content. Says Gilbert, "we are democratizing the experience of touring an art museum; we are offering a way for anyone to 'curate' their own little corner of MoMA."^[35] Since then, many museums have begun to realize that they can ride the crest of this wave, and many welcome a far flung audience to the table to participate in the creation of history, culture, and meaning. The Minnesota History Center invited Minnesotans to suggest topics for their October 2008 exhibition celebrating the sesquicentennial of the state. They received over 2,700 entries. Each of the 150 subjects chosen for display includes a photo and testimonial of the person who nominated it. Minnesota Historical Society director Nina Archabal asks, "Who better to tell us about Minnesota than the people who live here?"^[36] In March, 2008, the Brooklyn Museum in New York made an open call to artists to submit a work of photography that represented the theme "The Changing Faces of Brooklyn," along with a 100-word statement. Next they invited the general public to evaluate the submissions using an online evaluation tool. 3,344 evaluators cast 410,089 evaluations for the 389 entries. The photographs were curated by the crowd, and the top 20% were installed in the exhibition gallery at the Museum from June 27 to August 10, 2008.^[37,38] These online initiatives redefine the very nature of community—online visitors choose to join the virtual community based on personal interest, completely independent of their class, gender, ethnic profile, or national origin.

CONCLUSION

While there remain many bastions of curated culture that do not embrace the notion of accessibility and community involvement, the evolutionary arc of museums over the last 200 years tends toward greater inclusion. The introduction of first voice into a mainstream museum can offer new authentic and personal perspectives on a shared past. But just like the difference between memoir and biography, first voice narratives and mainstream historical analysis both hold value. In combination, they produce a synergy of meaning that provides empowerment and self expression at the same time as a sense of context in the overall course of human society. Mainstream museums can offer a stitching together of the patchwork of many first voice stories, but where the lines are drawn can be contentious territory. Museums and communities often struggle over who owns the narrative. These tensions are not limited to mainstream museums, as the politics of inclusion and exclusion play out in ethnic museums as well. Those in the dominant culture often consider minority groups to be homogenous, but a little interaction is enough to reveal the remarkable diversity within each group.

In spite of the challenges of community collaboration, it is one of the key strategies for museums to become and/or remain relevant. In an October 2008, keynote speech, Jonathon Katz posited that society is trending from empathy to agency. He cited the fact that the gaming industry, which operates on agency, has overtaken the gross sales of the film industry, which banks on empathy. He advised museums to embrace this trend toward agency, and to provide means for visitor influence on the content and experience in programs, galleries, and online.^[39] Nina Simon agrees; on her museum 2.0 blog, she says "In a world where visitors want to create, remix, and interpret content messages on their own, museums can assume a new role of authority as 'platforms' for those creations and recombinations."^[40] The museum of the future will prosper if it invites its visitors to enter the narrative process.

ACKNOWLEDGMENTS

I would like to thank Rosemary Adams, director of publications at the Chicago History Museum, for her editorial eye; Nina Simon for turning me on to the remarkable online museum community; my daughter Katie Biggs-Wrona for writing the insightful introduction; and David Kavesh for his relentless support.

Museums and Their Visitors: Historic Relationship

Samuel J. Redman

Department of History, University of California, Berkeley, Berkeley, California, U.S.A.

Abstract

The makeup of the museum visitor is perhaps one of the most challenging aspects of museum history for historians to uncover. Historians of museums have often noted that before the field of Visitor Studies grew to prominence, museums often envisioned their audiences as nameless, faceless masses. Historians have either painted this public as composed of members of the privileged elite or as those receptive to being shaped by the elite cultural institutions. This entry examines how the museum visitor has been discussed by both museum professionals and historians of museums in the nineteenth and twentieth century United States.

The Victorian museum visitor leaves but ghostly images in photographs and paintings of historic exhibition halls. Natural history museums greet the Victorian audience with objects grouped comparatively by type or geographic location, which form seemingly endless, straight lines within cold, glass cases. Art museums greet the same visitors with top to bottom walls of paintings or paintings along single lines intend to represent the development of art from its “primitive” forms to its highest (read) European incarnations. The Victorian museum visitor would hardly recognize most contemporary museums in either the United States or Europe, save for the seemingly timeless Greco-Roman architectural façade that masks the past century of change protected within the museum’s walls. Museum audiences and visitors, unlike exhibition spaces, collections acquisitions, architectural developments, and institutional changes, leave little documentation of their change over time. Historic visitors to museums have traditionally been treated by scholars in either one of two contradictory terms; they either represented the bourgeoisie elite of a given region or time period, or they have represented the faceless masses subjected to the social control of the elites governing the museums themselves. For more on this contradictory viewpoint related to museum audiences, see Conn.^[1] Other scholars have argued that American museums have, since their origins, been geared more towards educating broader audiences than European museums.^[2] Museums today, unlike their earlier manifestations, make deliberate efforts to empirically understand who their audiences are, how they learn, and what most interests them. This also helped allow modern museums make conscientious efforts to educate wide-ranging audiences, including children and the disadvantaged. Museums also increasingly work to include their visitors in their presentation of knowledge. Computer-based guest books, blogs, touch screen monitors, and other new technology allow visitors to “talk back” to

exhibitions and participate in their development. While most recognize these developments as being, on the whole, overwhelmingly positive, others criticize that museums have gone too far to embrace a brand of “edutainment” and long for a return of a museum “golden age” that, in truth, never really existed. In fact, the use of quantitative analysis by museums in efforts to better understand their audiences and how they learn has made museums both more effective and more enjoyable. This entry will attempt to trace the history of museum audiences and their representation in the historical literature. This entry focuses mainly on the history of museums in the United States from the late nineteenth century to the present. This entry does not focus on the growing body of literature focusing on professionalized Visitor Studies, but rather, it examines the nature of the more casual, yet concerted dialogue about museum audiences in which museum professionals engaged throughout the late nineteenth century to the present.

In his study of the intellectual history of American museums, the historian Steven Conn notes that, “Museum audiences are elusive quarry for the historian,” as “They left little trace of themselves and did not register with and specificity in the official records of most museums.”^[3] Before the 1920s, many museums understood their visitors in terms of one or two basic categories often limited a dichotomy of either adults or school groups. Many museums associated with universities differentiated between school groups and students from the university, sometimes even noting which courses required students to visit the campus museum. Beyond that, however, historians are left with only the museum professionals’ speculation on their patrons. Museums did not typically record the educational background of adults visiting the museum and their understanding of how to cater to their audiences continued to be limited. Generally, most museum archives are devoted primarily to the

maintenance of a record articulating the development of collections, general institutional policy, and exhibition spaces. Archives are perceived as generally silent on the subject of audiences; however, historians can gain clues to their nature upon close readings of the available sources. The contrast in the available documentation related to collections and exhibitions vis-à-vis the available documentation for museum audiences is perhaps telling. It might be argued that museums considered their collections and exhibitions as a greater priority to the health of the institution, leading directly to the ratio of available archival materials.

By the turn of the last century, museums and museum professionals were seriously contemplating the experience of the visitor to their institutions. Franz Boas, the illustrious cultural anthropologist working at the American Museum of Natural History (AMNH) engaged in just the sort of intellectual debate that characterized the discourse surrounding the experiences of the museum visitor during this time period in a 1907 exchange in the journal *Science*. In responding to a review penned by a curator at his former institution, the Field Museum of Natural History (FMNH) in Chicago, Boas chose to broaden the discourse and entitled his response “Some Principles of Museum Administration.” Boas, in comparing two institutions that were well known as significant research institutions vis-à-vis the sleepy American universities at the time, explains, “Museums may serve three objects. They may be institutions designed to furnish healthy entertainment, they may be intended for instruction and they may be intended for the promotion of research.” Boas was perhaps one of the most significant researchers working in the United States at this time and yet he explains in the article that the “value of the museum as a resort for popular entertainment must not be underrated.”^[4] Boas, despite much of what is said in this article, was never fully understood by historians to be a great popularizer. He also adds that, “every attraction that counteracts the influence of the saloon and the racetrack is of great social importance.” Museums, therefore, should be both entertaining and intellectually stimulating. George Dorsey, the curator from FMNH who initially offered his critique of the exhibits at the AMNH, longed for the good old days of museum exhibitions. Dorsey comments, “Such exhibits as those above [at the AMNH] characterized might with some degree of propriety be found in the lower grades of the public school, but they certainly do not seem worthy of an institution with claims to be foremost of American museums.” Dorsey argues that if the AMNH’s leadership truly desires for objects to serve the purpose of educating the general public, they should simply pack them up and send them off to the public schools around the region. He concludes condescendingly, “thus the ideal of this scheme might be more easily and cheaply realized.”^[5]

For many curators at the early part of the past century, however, museum exhibits were intended to be forums for

the presentation of the most recent available research. While the tension between creating cutting-edge research and the desire to popularize major ideas existed throughout the course of the twentieth century, several factors forced museums to begin changing. While a significant number of important exceptions exist, many of the top researchers in fields such as anthropology, biology, and geology began taking academic job posts in universities as opposed to curatorial positions in natural history museums. In fields such as ethnology and archaeology, the rise of new cultural patrimony laws governing the international transport of objects of cultural patrimony resulted in the decrease of certain types of collections arriving in museums. This claim is not without its problems. Certain institutions maintained, on the surface, a steady flow of objects into their collections, though, in the case of anthropological collections in museums, it is important to differentiate between archaeological and ethnographic material. The Hearst Museum of Anthropology at the University of California, Berkeley offers an example of this phenomenon. During the Great Depression and Second World War, when international travel and the purchase of objects from indigenous peoples became increasingly difficult, an increased number of archaeological expeditions allowed the museum to continue to grow at a steady pace in terms of the number of objects accessioned per year.

While the visitor experience was becoming more commonly discussed in various forums utilized by museum professionals, summations of the health of individual museums, or museums as a whole, began not with attendance figures but rather notable collections acquisitions and the development of research programs. Visitors were not left out of documents produced by museums entirely, however, and the visitors experience is hinted at on certain occasions. In a 1908 article summarizing the annual reports of several major institutions, F.A. Lucas notes that the Carnegie Museum’s annual report expressed dissatisfaction with the fact that the museum had been opened to the public before the exhibits were ready to host them.^[6] Lucas further notes the troubles of the Brooklyn Museum, which complained of having too many tasks without the necessary resources to address them. Two items that the Brooklyn Museum’s annual report disparages are a lack of labels for objects and disarranged exhibit cases. It does not take a vast leap of the imagination to begin to understand how a visitor might experience the self-described disarranged and unlabeled, exhibits of the Brooklyn Museum during this time period. Attendance figures, though not included in Lucas’ opening remarks on the health of American museums, are included in his commentary later on, presented alongside the attendance figures for several major institutions. Lucas notes that attendance figures, in his estimation, are commonly misunderstood:

We are accustomed to regard the number of visitors to a museum as a measure of its importance and public

usefulness, but it may more properly be looked upon as an indication of its interest for the public and to some extent the state of the weather. If it is of interest to the public, there is small doubt but what it will prove to be useful.^[7]

Lucas also gives an indication of how museums were beginning to understand their audiences. He notes that visitors to the U.S. National Museum (now the Smithsonian Institution) are largely out-of-town tourists, while many of the other major metropolitan museums, such as the FMNH and AMNH, host primarily local and regional residents. Lucas is also quick to point directly to the construction of a new, elevated train station in New York near the AMNH as the direct cause for a spike in attendance. Lucas writes, "Museum attendance, as shown by the report of the U.S. National Museum, is subject to great fluctuation and, like sun-spots, has its maximum and minimum periods." Lucas utilizes similar experiences from museums in London to conclude his analysis on the topic. Clearly then, museums were coming to a better understanding of their audiences by 1908, and this was starting to coalesce in the national and international discourse.

Art museums in the first half of the twentieth century understood themselves as serving multiple audiences. One of these audiences was the student of art. In 1915, Edith R. Abbot examined the experience of the art student as museum visitor in *The Metropolitan Museum of Art Bulletin*. Abbot notes that, "A sculptor comes to visit the classical collection. For him the antique marbles are all lessons in transcription; it is not enough to connect them with the past, their relation to the types of today is quite as pertinent." While these audiences were certainly welcomed to the museum, Abbot argues that the art student is best served by the museum by taking a guided tour, "with some one whose eye is . . . keen." Abbot also notes, however, "The instructor who is familiar with the resources of the Museum is in requisition in all of these instances as guide rather than as teacher. It is only when individuals or groups of persons arrange in advance for a series of appointments that museum instruction can be called organized in any sense."^[8] While articles like Abbot's lack the quantitative evidence utilized in later forms of visitor studies, it is demonstrative of attempts to examine anecdotal experiences to improve various types of visitor experiences.

By the late 1920s certain museums were attempting to better understand their audiences through quantitative rather than qualitative methods of observation. Instead of providing anecdotal evidence of the background of the audiences, or reporting casual curatorial strolls through exhibitions spaces in attempts to gauge how much audiences were learning, articles from this period, along with museum annual reports begin to demonstrate attempts at quantitative analysis. In the December 1929 issue of the *Pennsylvania Museum Bulletin* (now the Philadelphia Museum of Art), the museum reported the results of a

survey during the first year of its occupation of a new facility. The simple survey was given to one thousand of the first million visitors to the museum. The survey consisted of six basic questions related to the visitor's occupation, place of residency, mode of transportation to the museum, what prompted the visitor to come to the museum, what the visitor liked about the museum, and suggestions for improvement. The occupations of those visiting the museum represent rather basic categories separated into men and women, then subdivided into basic categories such as businessmen, salesmen, lawyers, doctors, and factory workers. Unsurprisingly, students represented the largest number of visitors in the male category. Tellingly, however, male individuals working in manufacturing were well represented in the survey; in short, the museum's audience was more complex than the anonymous hoards of art students assumed to have been visiting museums by previous estimates. The Philadelphia Museum of Art, unlike many of its counterparts including the Metropolitan Museum of Art in New York, was becoming well known as an institution that not only eschewed discouraging the working classes from visiting the museum, in fact, the museum worked to reach out to them. The Philadelphia Museum of Art also ran the School of Industrial Arts. Additionally, the museums advertisements on streetcar lines are indicative of this commitment to the working classes. For more on the development of the Philadelphia Museum, see Conn.^[9] To provide further evidence of this, lawyers, making up an estimated 6000 visitors, barely outpaced farmers, who represented 5000 of the 1,000,000 total. A majority of the art students visiting the museum were women (23,000), yet they were outpaced many times over by housewives (264,000). Housewives, in fact, represented over a quarter of the total number of museum visitors represented in the survey.^[10]

A vast majority of the visitors represented in the survey were from the metropolitan Philadelphia region, though a roughly equal number of visitors arrived from the suburbs of Philadelphia as did those from other regions of Pennsylvania (nearly 11%). A majority of visitors arrived to the museum by private car, though various types of public transportation, when combined, greatly outpaced this number. Over half of the visitors learned about the museum through word of mouth, though over 40% were prompted to go to the museum due to some form of advertisement, many of which were placed on streetcars. Housewives and farmers mostly enjoyed the period rooms, students and artists appreciated the paintings—as did the factory workers—and architects and engineers appreciated the museum building itself as much as they enjoyed the exhibits. The most common suggestion for improvement was a desire for a greater number of lectures, a desire for a café, and better modes of transportation to and from the institution. The museum report concludes that the institution does not simply represent a small portion of the public, but rather a large cross-section of the population. That said, the museum attracted, "a proportionally large

number of people from those groups whose vocations make them most dependent upon a knowledge and study of works of art.”^[10]

In reading the 1929 report on the Pennsylvania Museum’s survey, one is struck by not only the broad cross-section of the population visiting the museum, but also the wide range of reactions to the institution, most of which were positive. The report concludes that it was initiated in an attempt to better the museum’s service to the public. This report complicates the notion that museums in the United States were simply gathering points for the bourgeois elite of a given community. The vast number of farmers and factory workers visiting the museum indicate that it was not simply a form of entertainment for the upper class. Additionally, the roughly proportionate female visitors (54.8%) to male visitors (45.2%) indicate that museums were neither sites of male or female domination.^[10]

Though quantitative forms of analysis were becoming increasingly available, broad assumptions related to museum audiences and visitors remained the currency of academics and museum professionals that attempted to be the authority on the subject. In a 1940 article appearing in *Science*, Marcus S. Goldstein posited a number of questions on museum visitors but then noted, “I am not acquainted with the literature on museum administration, and research based on the above queries may already be available.” Rather than familiarizing himself with this literature, Goldstein believed his assumptions, and the assumptions of those around him, to be interesting enough for publication, “In any case, my own observations (and the response of a number of other individuals with whom the subject has been discussed support these views), point to the following conditions. . . .” While many of Goldstein’s arguments prove to be interesting and valid, (e.g., museum exhibitions should have movement to attract a broader audience) a complete lack of evidence beyond his assumptions prevent the argument from being wholly effective.^[11]

The experience of visiting museums in both the United States and Europe changed swiftly after the close of the Second World War. Museums in the United States began hiring educators who worked directly with visitors, curatorial staff, and perhaps most importantly, the docents who guided tours through museum exhibits. Docents were trained to guide tours aimed toward educating specific types of audiences, rather than repeating the same tour for every group. Art museums, specifically, had taken the lead role in working with young children in the field of museum education following the Second World War.^[12] More specifically, art museums in cities like Indianapolis, rather than the major metropolitan museums of Chicago or New York, assumed the lead role in developing children’s art classes or workshops in museums. In addition to developing new exhibition spaces specifically aimed at childhood education, museums were changing the nature of how school groups visited museums. Whereas previously

museums would encourage school groups to tour the entire museum in a single day, museums such as the Denver Natural History Museum (now the Denver Museum of Nature and Science) began encouraging teachers to tie visits closely with classroom materials. By the late 1950s, museums were discouraging schools from bringing in groups for general visits, and strongly encouraging these types of classroom-related visits. An example of this type of guideline can be found in its annual report.^[13] Attendance in museums in both the United States and in many places in Europe boomed following the Second World War. Long lines awaited newly reopened museums on the coasts or in vulnerable areas including the British Museum in London and the Metropolitan Museum of Art in New York, both of which had been closed or redacted during the course of the war. The Denver Natural History Museum, Art Institute of Chicago, and numerous other American museums broke attendance records as the Second World War came to a close. Americans, as the war waned on, possessed a far greater amount of disposable income than during the latter years of the Great Depression, and one manner in which they spent their new income was at museum turnstiles. Theodora Kroeber, wife of the famed American anthropologist, Alfred Kroeber, describes in her biography of her husband their waiting in line with throngs of Londoners to visit the reopened British Museum of Natural History.^[14] Museum visitors again availed themselves to many of the most prized works of arts possessed by these institutions that were placed in storage or sent inland, to other museums for safekeeping.

By the 1950s, in addition to changing methodologies related to collections, loans and exchanges, the goals of various types of museum exhibitions, were continuing to evolve. In 1957, the *Los Angeles Times* described the development as the museum shifting its gaze from the exhibition cases themselves to those that were supposed to be looking at the cases. The *L.A. Times* reporter argued that when museums did in fact begin to attempt to understand the museum visitor, it noted that they were generally uninterested in many of the ideas presented to them. “Perhaps,” the *L.A. Times* reported, “it was because the presentation was uninspired.”^[15] Generally, museum curators by this time were taking fewer risks in their exhibitions. By 1954, a pair of museum commentators and curators, Donald Collier and Harry Tschopik, Jr. commented in *American Anthropologist*, “Most importantly, the newer exhibits have not, to date, reflected any systematic or integrated plan, and treatment of many problems of current theoretical interest. . . .” Unlike museums of the first half of the twentieth century, exhibits did not address matters of “current theoretical interest.”^[16] Instead, museums presented basic educational materials and served as introductions to broader topics. Museums had become more analogous to introductory textbooks than scholarly journals. Interestingly, the notion of educating the public via exhibitions and the production of top-notch research continued to be

somewhat at odds. This was especially true in university-based museums. In 1953, in discussing the continued desire for a new anthropology building, the anthropology department at the University of California, Berkeley circulated a memorandum that noted museum research and the use of collections for exhibition spaces were somewhat at odds, “The use of the collections for undergraduate teaching exhibits frequently conflicts with their use for research, when materials in an exhibition case are needed for a research project, and the reverse situation also arises.”^[17]

Popular notions surrounding museums, however, were anything but fully changed by the 1960s. In 1963, another *L.A. Times* reporter argued that if the word, “museum” came up in a word association game, his response would be “stuffed Indian.” This word association response, the reporter then argues, would have been inaccurate, “Because museums are moving magically these days.”^[18] The postwar period of American history also meant the development of new museum facilities in many parts of the country. This development, in turn, led to greater pressure for museums to draw larger crowds. Museums began responding to these pressures by hosting a greater number of major, “blockbuster” exhibitions on topics of popular interest, thus changing the visitor experience.

While most museums were essentially developing educational programming without quantitative analysis informing the decision-making process, museum professionals during the 1960s and 1970s worked to better understand their audiences and develop programming specifically attuned to the need of the public. In 1975, an article in the journal *Studies in Art Education*, estimated that 93% of the art museums in the United States sponsored educational programs. Of those programs, no serious, systematic documentation of the programs’ effectiveness or scope had been attempted. In other words, while museums were attempting to educate their audiences utilizing more refined processes, they possessed little understanding of how well they were working.^[19]

By the late 1980s and early 1990s, museums were arriving at a more complex understanding of their audiences. In 1989, a study of several American art museums that corroborated with another study in England demonstrated that those visiting art museums were typically “in the upper educational, occupational and income groups, younger than the population in general (average age is 34) and active in community and leisure-time organizations.”^[20] While natural history and science museums were understood as catering to audiences differently than art museum, the common notion that museums were synonymous with the upper class of western society continued to stick, and arguably with some supporting evidence. One of the authors of the 1989 study, would, 1 year later, argue that the one of the most important factors in turning a nonart museum visitor into a regular patron was not parental encouragement or the entrance into a new tax bracket, but rather, having art lessons as a child. The most important factor however, between visitors and non-

visitors, was simply being offered the opportunity to visit the museum in the first place.^[21]

In 1999, the Smithsonian’s National Museum of American History featured an exhibit on the history of sweatshops in the United States. The exhibit, which covered a subject that was challenging for many visitors to the museum, provided a guest book for visitor comments. Mary Alexander, an educator employed by the Smithsonian, published many of her observations related to the visitors’ reactions and comments to the exhibit, which was entitled, “Between a Rock and Hard Place: A History of American Sweatshops, 1820–Present.” The following year, the results of Alexander’s study were published in the academic journal, *The Public Historian*. The exhibit is representative of attempts by museums to better understand—and subsequently cater to—their visitors. The process of documenting the audience’s reactions to an exhibition, studying these reactions, and then disseminating the results of the study in an academic journal would have been unheard of throughout most of the twentieth century. As Alexander’s study demonstrated, museum audiences were, by-and-large, understanding many of the complex and challenging themes presented in the displays. Alexander reported the comments of the visitors to museums in a fashion that might surprise some, arguing that their comments were “intelligent, articulate, sophisticated, and sometimes vehement.”

Several years before the Smithsonian exhibition on sweatshops in American history, the American Association of Museums developed a report entitled, “Excellence and Equity: Education and the Public Dimension of Museums.” The report examines museums and spaces of public education and offers 10 guidelines for improving and maintaining the role for museums well into the future. For the American Association of Museums, the changes occurring related to the professionalization of museum education represented progress. Analysis of this document can be found in Crew.^[22] The changes occurring in museums during the closing decades of the twentieth century did not go undisputed. In 1991, John Terrell, a Curator of Anthropology at the FMNH compared the contemporary museums to Disneyland, calling for a return of, “The Good Old Days,” when academic departments were responsible for the development of exhibition spaces. The problem with Terrell’s commentary, however, is that “The Good Old Days,” as he envisions them, never really existed. Terrell notes that while museum curators were responsible for exhibitions from the founding of the museum through the 1960s, the museum displayed some of its most popular exhibitions. What Terrell carefully ignores, however, is that some curators were not simply just “mediocre in their exhibit talents”; some curators deliberately misled the public and the press in order to push for greater attendance, including a notable example of Henry Field at Terrell’s own Field Museum in the display of a set of European human remains from the

Magdalenian Period. (Henry Field, upon the occasion of the display of the Field Museum's Magdalenian Girl.) Field called the display of the specimen a "chance to fire the imagination of Chicago."^[22] In connection with the skeleton, Field purchased an ivory harpoon point he claimed to have been found near the remains. Field began referring to the projectile point as the possible cause of death for the woman, and labeled it in the exhibition space as such. No archaeological evidence exists to make this claim, and it is unclear as to whether or not the projectile point even came from the same site at all. Despite the tenuous nature of the evidence, however, Henry Field, the museum, and the popular media, eagerly ran with the story. The museum and the press further speculated on the story of Magdalenian Girl's murder as coming at the hands of a jealous lover. By the time the remains arrived in Chicago, the press had latched firmly onto the story, splashing it on the front pages and further speculating on the circumstances of the prehistoric woman's death, and the public became fascinated. The first Saturday of her display, 22,000 visitors, a record crowd, came to view the skeleton firsthand.^[23] Despite the fact that over a decade had gone by since her first appearance in Chicago, lectures on the subject of Magdalenian Girl were still selling out following the Second World War, as long as they included dramatizations of the circumstances of her demise.^[24] In other words, possessing a doctorate in an academic discipline (like Henry Field) does not prevent an individual from being disingenuous or an effective communicator. On the other hand, educators with specialized knowledge of communicating ideas on a broad level have, on the whole crafted exhibits in museums which are arguably more interesting and entertaining than those developed by previous generations of scholars. My point here, of course, is not that educators are above the human temptation to exaggerate claims or make mistakes, but rather, that academic credentials does not prevent these types of errors. Like Dorsey before him, Terrell misjudged the modes of crafting the visitor experience in his own day-and-age. In the interest of full disclosure, the author is a former employee of the Field Museum.

Terrell and those still pining for a return to an age before the professionalization of education departments within museums would be wise to heed the words of A.E. Parr, the director of the American Museum of Natural History, who wrote upon the conclusion of the Second World War,

"... to see as the goal of reconversion only a reversal to an earlier state of happier memory, and to seek mainly the reestablishment of previous contacts with fellow sufferers rather than attempt to reenter the turbulent main stream which left them on its shores for a while. This is the deepest pitfall across the path of the natural history museums today."^[25]

Museums today understand their visitors and audiences much more effectively than throughout the course of most

of their history. Anecdotal assumptions about what makes a museum effective have been replaced in a successful manner with quantitative analysis. While visitor surveys and the hiring museum professionals with backgrounds in education have proven to be a positive development for these institutions, they cannot fully replace the casual observation of exhibition halls on a day-to-day basis. Curators would be well served to spend more time in their own exhibitions, working directly with visitors and observing docent tours rather than assuming they understand their constitution. Additionally, curators should avoid the assumption that their galleries were either more effective or possessed some a greater form of academic rigor in the "Good Old Days." While museums at the turn of the last century did, in fact, present a more complex exhibition of their subject matter, the over-verbalization and emphasis on theory made many exhibits more pedantic than effective. While the Victorian museum visitor would hardly recognize most of their own cultural institutions, museums, and their audiences, have largely profited from these developments.

Museums as Place

Peter Davis

Han-Yin Huang

International Centre for Cultural and Heritage Studies, Newcastle University, Newcastle upon Tyne, U.K.

Abstract

Theoretical approaches to place have been the domain of geographers, sociologists, psychologists, and, to some extent, museologists and academics with an interest in culture and heritage. This entry positions museums within these theories, in particular exploring how contemporary museum practices deal with place representation. Particularly relevant here are the changing nature of places caused by globalization and migration. Alternative approaches to exploring places enshrined in the philosophical approaches of ecomuseology are also discussed.

INTRODUCTION

Place is a complex concept, and few places are as potentially emotive as the museum environment. Place is inevitably linked to concepts of identity and community; museums attempt to construct the identities and histories of places and their communities, making them institutions with challenging responsibilities. This entry reviews the theoretical approaches to places that have been explored by geographers, sociologists, and psychologists and attempts to position museums within them. Globalization and the changing nature of places are of increasing relevance to museums and are discussed briefly before exploring views about place representation enshrined in the philosophical approaches of ecomuseology. Here geographically defined places and the complexities of their landscape, natural resources, archaeology, history, and contemporary culture offer an alternative museum model for the celebration of the tangible and intangible characteristics of place.

THEORIES OF PLACE AND THEIR RELEVANCE TO MUSEUMS

... Les Salants is dead throughout the summer, panting and parching in the wind and heat. But to me, it's still home. Not the most beautiful place in the world, or even the most welcoming. But it's my place

—Joanne Harris, *Coastliners*

The image that Joanne Harris paints of her fictional village of Les Salants, located on a small island off the coast of Brittany, France, is that of an imperfect place; isolated, desolate, and inward-looking, it is a place rich in family rivalry and feud where the community scrapes a living

from the sea. Nevertheless, despite its frailties and uncertain future, for the central character it remains “my place,” a place—according to the islanders—to which “everything returns.”

All people have their own place, or perhaps several places, where they feel they “belong.” Terms such as “belonging,” “sense of place,” “identity,” and “community” are all related to—or confused with—ideas about place. Perhaps it is unsurprising then that place, and the more elusive “sense of place” have been a research focus in several disciplines, including geography, anthropology, ecology, psychology, sociology, and cultural and heritage studies. A variety of terms seeking to capture the relationship between people and place, including “sense of experience,”^[1] topophilia,^[2] place identity,^[3] place attachment,^[4] and insidedness, local sentiment, or community sentiment^[5,6] have been coined. Discussion has sought and found inspiration from cross-disciplinary evaluation.^[7–9] So, for example, although the physical geographer may examine place as a defined geographical entity, “the sentiments of attachment and detachment that human beings experience, express and contest in relation to specific places”^[8] have been increasingly examined by human geographers as a result of psychoanalytical, social, and environmental approaches. Place lies at the heart of human geography^[9] with Yi-Fu Tuan, Edward Relph, and Anne Buttimer being regarded as pioneers in reflecting on place and “sense of place” from experiential perspectives.^[10,11] These three authors’ understanding of place puts people at the heart of the concept. Tuan^[12] reminds us that a sense of place goes beyond aesthetic appreciation, while Relph^[13] demands that we examine the idea in terms of “authenticity”; Buttimer^[14] argues that place is something that must be experienced rather than described. All emphasize that place provides “a world of meaning.”^[11]

Tuan^[15] sees space and place as mutually defined terms: “what begins as undifferentiated space becomes place as we get to know it better and endow it with value.” Similarly Casey agrees that the place must be experienced: “there is no knowing or sensing a place except by being in that place, and to be in a place is to be in a position to perceive it.”^[16] This has resonance with Escobar’s^[17] view that place is not simply “a constructed reality”—a physical space—but it is also “a category of thought,” a conceptualization of identity. This is an important issue for museums, because they also seek to conceptualize place. Museums also add an additional layer of complexity because they frequently attempt to portray a place not only as it can be experienced today, but also seek to create a vision of a place at an earlier point in history. Museums may attempt to take us back to the mediaeval past when discussing social histories, or deep into the Mesolithic to explain archaeological finds, or into the Mesozoic to explore dinosaur diversity. Dioramas of environments, re-created streets, house interiors, immersion habitats, and digitally created worlds are all utilized by curators and designers to create illusions of places past and present, attempting to provide a “real” and truthful experience.

There is an interesting contrast then between the illusion of places and events that museums create within their walls, and the experience the visitor has at a heritage site. These *in-situ* encounters with place and the past become part of our lived experience and may—arguably—be more meaningful as a result. Smith^[18] regards this “affect” of place as being of particular significance in order to understand the meaning of heritage and heritage sites. She writes:

Heritage as place, or heritage places, may not only be conceived as representational of past human experiences but also of creating an affect on current experiences and perceptions of the world. Thus, a heritage place may represent or stand in for a sense of identity and belonging for particular individuals or groups.

If the word “museum” is substituted into this paragraph for the term “heritage” it makes equally sound reasoning. The idea of place is vital to our understanding of the significance of museums to society, helping us to comprehend—and question—the role museums have in constructing identity.

Place theories make us ask what meanings and values are museum buildings—as place entities themselves—endowed with? With their imposing architecture and sense of power, permanence, and purpose museums are an essential feature of our mental maps of familiar places. They are a reference point in our physical landscape and help us to navigate spaces. So, for example, the museums that grace the waterfront of Stockholm (Sweden) are signifiers and guides to the physical and cultural landscapes

for local people and tourists alike. For the local person with a strong attachment to place and memories of childhood (and later), visits to a local museum building are also significant in placing museums within our cognitive geography. It is accepted that memory and place are strongly connected and Casey suggests that “we might even say that memory is naturally place-oriented or at least place-supported.”^[19] Hummon^[5] also addresses the social dimensions of place and the emotional investment and meanings attached to it. Of especial interest to museums are his views on the personal and social meanings of place, how a “symbolic locale”—such as a museum building—serves as an extension of self and community identity. For many people then, museum buildings are a part of the tangible landscape and consequently important in their own right through providing a beacon for a sense of belonging and a symbol of permanence.

The notion that “place provides a world of meaning”^[11] demands that we question how museums construct and convey meanings and values about a place—its history, its natural environment, its cultural landscape, and its people—and how they represent a range of identities and memories. How do museums help their visitors to position themselves within a community, to find a “place” in the social, cultural, and physical world, to affect them? Museums are a cultural tool that societies, communities, and even nations have used to construct and express a sense of identity and belonging, but what elements of place feature in the collections held by museums, and are there restrictions on what can be exhibited to represent place? How are objects selected from this store of artifacts to construct “truth,” a narrative about a place, peoples, histories, or events that took place there?

Before exploring these ideas further, it is essential to discuss the nature of museums themselves. All museums are not the same, indeed, their diversity is extraordinary. They can be managed and financed centrally by the state, by local authorities, by charitable trusts, and by private individuals. They may exhibit specialist collections or hold a diverse range of artifacts and specimens. They may have high levels of funding and professional staffing or be small volunteer-run institutions. They may identify their audience as being international or national tourists, or only local people; they may appeal to elite audiences or they may regard themselves as being family oriented. They can be located in large cities or in remote rural areas. All these variations influence how individual museums determine their role in society, and consequently how they might wish to interpret their place. What image of “their place” might they attempt to portray in their exhibitions, and who makes those decisions? It is evident that the complexity and diversity of museums make it dangerous to generalize about the relationships between museums and place.

The situation is complicated further by the types of collections that museums have amassed over time.

Collections may be of international scientific and historic interest or be of purely local significance. Collections can have immediate or explicit links to local places (a locally collected herbarium, a collection of local landscape paintings, or ceramics from a local pottery) or may gain an association with a place over time, an inferred link. Thus a stuffed polar bear or a collection of French impressionist paintings held by a museum in an industrial northern city in the United Kingdom might not have explicit links with the immediate locality. Nevertheless, generations of local visitors have “appropriated” them; for local people these items constitute elements in the memories and knowledge of “their” museum in their city, they have become a part of their place.

Where does this leave National Museums and their “universal” collections? Large national museums, such as the Smithsonian, the British Museum, or the Louvre, portray a global view of place. The British Museum, for example, does, of course, hold collections which enable it to interpret aspects of British history but most of its galleries present a global perspective, using artifacts to celebrate ancient civilizations and the diverse cultures of the world. These exhibitions also represent Britain and the British as traders, explorers, and especially, as colonists. Objects exhibited here are not only a testament to humankind’s ingenuity and craftsmanship, but also a record of the acquisition of places and their natural resources, and of the subjugation of people. Perhaps it is unsurprising that the objects themselves, rather than people or place, are the principal focus of interpretation in the British Museum. For this reason much of the following discussion ignores national museums, as they say little about the more familiar places within which we locate ourselves.

What then are the key theoretical components of place that museums have to consider in relation to their audiences and their exhibitions? Relph^[13] places particular emphasis on time, suggesting that the length of time in a locality appears to play an important part in how it is perceived by the individual; other studies^[20] support the view that the longer a person stays in a place, the more strongly he or she is attached to it, and especially so if they were born there. Attachment may therefore differ between long-term residents and more recent immigrants.^[15,6] However, recent research^[21] in Lancashire (United Kingdom) has revealed that incomers have an ability to place themselves “in an imaginary landscape which is central to people’s sense of belonging.” The authors refer to this phenomenon of contemporary attachment to place as “elective belonging,” where “Belonging is not that of an individual to a fixed community rooted in place, but rather, one in which the place becomes valuable to the individual.”^[22] It appears that incomers grasp the opportunities places make available to them, and that they frequently become involved as active players in local social networks. Tuan^[12] suggests that an individual’s perception of place

also varies according to the stage of life he or she has reached, but other variables—for example, gender, education, religion, class, occupation—must also surely come into play. The nature of the person–time–place interaction demands that museums be aware of its complexity and of the range of knowledge about and attitudes to place that occur among its visitors. Long-term residents may have a very different place identity to that of more recent arrivals, but the latter may be more receptive to innovation by, and participation in the museum.

Museums can be confident that even though every individual has their own unique concept of place, strong elements of place are frequently shared with others.^[23] So, for example, in the redesigned (2007) galleries of Sheffield’s Weston Park Museum, two of the elements chosen to represent Sheffield (United Kingdom) as a distinctive place are its past and current involvement in the steel and cutlery industries, and the contemporary natural history of the wooded river valleys that are so characteristic of the city. The link is made between the valleys and their industrial archaeology as it was here that water powered early industrial activity. These attributes have been interpreted by the museum’s professional staff using a range of local objects and specimens from the collections, but also using local voices and experiences—in text and oral/visual presentations—to provide meaning.

The dynamic interaction between people and place—the creation of the cultural landscape—is particularly significant for museums. Lippard^[24] suggests that every individual interacts with place differently, whereas Agnew^[25] proposes that “Common experiences and interests create an emotional attachment and self-definition peculiar to the specific place in which the locales of enduring social relationships are concentrated. This is local identity or sense of place.” It would seem that this author regards a shared local identity as being the same concept as sense of place. However there are dangers for museums in these imagined, shared identities, the ways that communities “remember” the past. Watson^[26] illustrated how the subject matter for the new (2004) Great Yarmouth (United Kingdom) museum became focused on the herring fishing industry, the theme chosen by local people during an extensive consultation process as the most significant historical narrative for the town. Fishing surpassed all other suggested topics despite the fact that it was (short) seasonable work that even in its heyday (1913) employed only a small percentage (5.6%) of Yarmouth people. By 1968, only five boats were active and the demise of herring fishing in 1971 was not publicly mourned. Historical research indicated that other industries—especially tourism, and silk and crepe manufacture—had been far more important in establishing the town’s prosperity. However, in popular imagination, fishing had a deep historical legacy; it was a picturesque tradition where people lived in harmony with the sea and the coastal landscape, something that Great Yarmouth

people could identify with and be proud of. As a consequence, the new museum has proved to be popular and has been significant in restoring local pride. Due to the widespread public consultation, and the strength of collective memory about the fishing industry that this demonstrated, the museum had little choice but to embrace a myth about place and reinforce it.

So can museums ever construct and celebrate an “authentic” or “truthful” sense of place? By carefully selecting artifacts and stories that trigger an emotional response they may have the ability to do so, reminding visitors of significant moments in local history, or—as in Sheffield Museum—introducing the past through engaging media such as oral histories and by introducing the visitor to key elements of the tangible and intangible cultural landscape. However, Watson’s^[26] research reminds us that museums must recognize the complexities of place and history and Lippard^[24] hints that place must be interpreted from multiple perspectives. This is important for museums if seeking to reach a wide audience, and especially so when dealing with “difficult” histories. For example, Crooke’s^[27] discussion of the presentation by museums of the contested histories of conflict in South Africa and Northern Ireland clearly demonstrates the value of presenting multiple, contested viewpoints about places and their histories.

Identity, including place identity, is not only socially constructed but also constantly shifting. Thus although the distinctive characteristics of places can to an extent be quantified at a point in time by identifying key tangible and intangible elements, for example using the “Parish Maps” and “Illuminated Alphabets” promoted by Common Ground,^[28–30] the dynamic nature of “local identity” and “sense of place” is much more elusive, it is a chameleon concept. Shifting identities pose a real challenge for museums and demands that they collect contemporary evidence to represent changes in place. Some disciplines in museums, for example, art or archaeology, find this more challenging than others. However, other museum specialists—social historians, anthropologists, and natural scientists—are continually documenting change not only by collecting objects and specimens but also using digital recording media. So while not all museums will dedicate efforts to this goal contemporary practices in collecting have been reviewed by many individual museums. At Te Papa (New Zealand):

Since the early 1990s, collection development has increasingly aimed to represent the visual culture and history of Pacific peoples in New Zealand. The scope is broad and ranges from contemporary high art and fashion through to new forms of weaving, *tīvaevae*, and *tapa* that migrants have brought with them to New Zealand. Complicating this changing curatorial focus is the fact that many island-based communities have become more transnational in nature as a result of developments in telecommunications, air travel, email, and print media.^[31]

Such strategic approaches to documenting a changing material culture that reflects place are now a feature of most museums’ collecting policies. Museums—as Te Papa does—must also acknowledge that new communication media enable people to be more aware of their place by making comparisons with the homelands of other communities.

The dynamic and emotional dimensions of place enable Cresswell^[9] and Lippard^[24] to propose that place is somewhere to be lived, experienced, and explored from inside. In contrast, an outsider, or visitor, can only observe “landscape” as they lack the longer term, intimate experience of a place. Similarly, Cross,^[6] proposes that sense of place is comprised of two aspects: relationship to place and community attachment. Anyone can build a relationship to place, even temporarily as a visitor, but she emphasizes that communities—insiders—relate and attach themselves to a place in many ways, and that those processes and feelings about place are dynamic. Hummon^[32] also sees sense of place as having two separate features, namely an interpretive perspective on the environment and an emotional reaction to it. While these theorists fail to address how the transition from outsider to insider, or from not belonging to belonging occurs, these views suggest that museums can never really provide a true experience of place for insiders, those communities that belong. Museums can interpret place but cannot convey the emotional dimension that locals have, simply because emotional attachment to place lies in the locality, not inside the museum. This is something of a paradox as most local or regional museums regard local people as their key target audience. So in order to best interpret place in museums, we firstly need to be aware that continual revision of ideas and concepts in exhibitions is necessary to successfully capture its dynamic local nature and secondly, to try to provide an emotional, affective experience. Ultimately museums have to make choices not only about the vision of place and the histories of place that they wish to portray, but also *how* places are interpreted. To really affect visitors they need to employ a full range of media and innovative design techniques, but in truth full representation of place will always be out of reach, an illusion.

If place theory tends to suggest that most museums will deliver an interpretation of place for consumption by “outsiders,” this may help to explain patterns of museum visiting by holiday-makers or tourists to local museums, where people are making an investment of time in order to better understand a place. However, these theoretical approaches fail to totally explain why some museums (such as Glasgow Museums, Scotland, or the Watercolour Museum, Tjörn, Sweden) appear to develop an emotional relationship with their local communities, encouraging ownership and involvement, while many other museums fail to do so. O’Neill^[33] links the success of Glasgow’s museums in terms of community relationships to the organization’s drive to create a more positive identity of the city and its

people, so that it is a place its inhabitants are proud to belong to.

Proshansky et al.^[34] use the term “place identity” to approach this issue of how individuals react to “their place,” linking their ideas to notions of the self, or self-identity. They define place identity as “... cognitions [that] represent memories, ideas, feelings, attitudes, values, preferences, meanings, and conceptions of behavior and experience which relate to the variety and complexity of physical settings that define the day-to-day existence of every human being.”^[35] The authors attribute five functions to place identity, namely recognition; meaning; expressive-requirement; mediating change; and anxiety and defense. Of particular relevance to museums is the recognition function, which affirms a sense of continuity and environmental stability by allowing an individual to recognize their physical world; museum exhibitions can reinforce feelings of historical attachment and permanence of place. The “meaning function” that serves as the source of an individual’s perception of place and their behaviour is also interesting in terms of how visitors react to museum environments or “museum places”; quiet and reflective gallery spaces may play a role in allaying anxiety. The notion of mediating change is interesting for museums, and may help us to understand how Glasgow’s museums (mentioned above) have created an emotional bond with their local communities. The transition from once industrial city to a city of learning and culture has certainly been aided and supported by the museum’s vision of Glasgow as place; here we observe the museum as both mediator of change and advocate for place.

For Proshansky et al., place identity is predominantly cognitive. By contrast, Dixon and Durheim^[36] propose a discursive approach to place identity, relocating its construction from “the vault of the mind” to “the flux of human dialogue.” They suggest that actions such as “blaming, justifying, derogating, excusing, excluding and all of the other things people do with words” construct place. Museums can be identified as an element in this “flux of human dialogue”; they have the potential to act as an inclusive venue for discussion about place identity with their communities. The need to consult with all communities is especially important for museums, where the concept of multiple voices and multiple interpretations of places and their histories is gradually being accepted. Previously “hidden histories” and untold stories have begun to emerge as part of wide-reaching postmodernist changes in practice in museums.^[37,38]

PLACE, COMMUNITIES, AND IDENTITIES IN A GLOBAL WORLD

In the early 1990s, globalization theorists revitalized concerns about the demise of local identities, the loss of place. They argued that due to the movement of peoples, objects,

capital, and information across large distances, life for most people is not restricted to one place, to a defined locality with fixed boundaries. New media of communication played a crucial role here, enabling rapid contact over long distances, leading to the instability and fragmentation of face-to-face community exchanges, which for some writers^[39] was the essence of social life. Other developments—shopping malls, corporate logos, fast food—pointed to the dilution of the unique nature of places and the emergence of “placelessness.”^[13]

However, by the mid-1990s, a different view of globalization began to appear^[40–42] that explored how globalization could encourage the reworking of social relationships and generate new approaches to localization. Central to these arguments are that place, or the local, are not subsumed by the national or international, rather that nation or the region are composed of innumerable places; in Lefebvre’s words “the worldwide does not abolish the local.”^[43] Robertson popularized this view as “glocalisation” where “globalisation has involved the reconstruction of ‘home,’ ‘community,’ and ‘locality.’”^[44]

So how do we think about our place—the local—within a globalized world? Massey’s^[41,45] views on “progressive sense of place” are especially helpful as they demonstrate how individuals move into and out of places; this can happen irregularly or with a regular pattern. Massey regards “coming and going” as crucial to understanding how people develop or perceive their relationship to place. The implication here is that knowing another place, or other places, is essential to understanding your own. Appadurai^[46] takes this argument a stage further by suggesting that localities are socially produced through processes of boundary definition; delineating the boundary of place is achieved by making comparisons—aided by global flow—with adjacent places. Individuals and communities create a shared identity that provides boundaries that lie beyond physical features such as fences, walls, rivers, or mountains. The line drawn between communities, between places, is socially constructed, invisible, and dynamic, and often difficult to define.^[9,39,47] Consequently globalization makes us question firstly the nature of the communities museums are attempting to serve, and secondly how local places should be represented by museums in terms of the different reconstructions of “locality” and “place” influenced by globalization.

One major feature of globalization is the movement of peoples. Hall^[48] refers to the concepts of the “contact zone” and transculturation to explore how culture and identity is constantly changing through these interactions and mutual influences. He argues that intense encounters with different cultures, where one identity negotiates with the “copresence” of another identity or identities and where elements of cultures fuse together, lead to identities with multiple frames. Diaspora discourse has been significant in terms of understanding place; indeed, these views

about shifting cultures are also true for place identities. Consequently museums must try to acknowledge and reflect such dynamism. No single identity is pure and is “always already ‘the product,’ in part, of a long history, of connections with the beyond, with other places.”^[49] A place can also be “hybridized” under multiple influences through the passage of time, and museums need to respond to and document such change. One relevant example here is Sheffield Museum’s (2008) temporary exhibition on Sudanese immigrants to the Yorkshire city, which explored the reasons for their migration, the ways in which they have adapted to new lives and developed new communities, and how they feel now about their homeland. Similarly Tyne and Wear Museum’s temporary exhibition (2008) “Destination Tyne and Wear” uncovered and described the history of the region’s migrant communities and demonstrated how they helped to shape its culture from the nineteenth century onward. Immigrant voices are used to give powerful and emotive recollections of movement and settlement, demonstrating how the import of new ideals, new cultures, has enriched the region, creating a new, vibrant, and changed culture. The exhibition reflects on the ways that the region has become a different place, but one that all its inhabitants can share pride in.

Some observers feel that immigrant individuals and families cannot immediately identify with places (and hence their museums) because they are strangers; this feeling of “not belonging” can be even stronger for refugees and exiles “who did not leave their homes voluntarily.”^[50] However, this conclusion is refuted by researchers who, in relation to their study group in Lancashire, state that

... we agree with proponents of globalization theory. Although in our four locations there continue to be people who live in the vicinity of where they were brought up, these are not necessarily the people who feel they belong there. It is the perceptions and values of incoming migrant groups, which more powerfully establish dominant place identities and attachments ... people’s sense of being at home is related to reflexive processes in which they can satisfactorily account to themselves how they come to live where they do.^[51]

This research is significant for museums, reminding them that incomers rapidly adapt to new places and adopt a sense of belonging to that place. Strategic approaches for museums require inclusive recognition of its multiple communities.

Interestingly, Halls’ “back-to-basics” model of cultural change, invites a different response to globalization, one that turns inward to more “closed” definitions of culture and place with “the revival of an attachment to more ‘local,’ or fixed, or placed aspects of culture.”^[52] This model is reflected in the continuing growth of small museums dedicated to celebrating place at a local scale. The *hembygdsmuseum* movement in Sweden, for example,

a network of some 1400 small social history museums, seeks to capture and even fossilize place and time by conserving vernacular houses, landscapes, and their associated material culture.

Similarly, concerns for the general “loss of place” has led to movements which emphasize local culture and heritage and attempt to defend local distinctiveness. However, Harvey^[39] notes that place is always subjected to influences beyond its immediate boundaries and consequently by the need to adapt. Places compete against each other for capital investment, production, and consumption, yet decry the loss of distinctiveness and authenticity. Similarly, Massey^[47] argues that places cannot be understood without the “consciousness of its links with the rest of the world” and asks that the possibility of developing a progressive, “global” sense of place be considered. This global responsibility is echoed by several new museums, including the Museum of World Culture in Gothenburg, Sweden, which promotes the world as place, and creates exhibitions on subjects such as *Aids* and *Human Trafficking* that reflect connections across the world rather than divisions and difference.

PLACE AS MUSEUM

Interestingly, Tuan regarded museums as poor channels to communicate place because “[t]he museum, after all, consists wholly of displaced objects”^[53] and “[t]he effort to evoke a sense of place and of the past is often deliberate and conscious.”^[54] Tuan rejects the creation of a sense of place using artifacts and artificial situations. Other researchers^[55] have similarly suggested that:

It might be argued that the complexity of place and what it represents to individuals and communities [means] that the traditional museum can never capture its elusive qualities. It is impossible for the curator to acquire place, carefully label it and store it in an acid-free container. Museums can acquire fragments of place, and exhibit them together to re-create their version of place, but that is all. The essence of place lies beyond the museum, in the environment itself, and is defined by the individuals and the communities that live there.

So is a different museum model required to try to capture and celebrate places? Place theory indicates that individuals and communities attach deep significance to their place and particular sites within it. Various mechanisms exist to conserve the sites or objects that possess special significance, at every level from the World Heritage Site to the Tree Preservation Order. So, for example, in England the preservation and interpretation activities of English Heritage, Natural England, and the National Trust have helped to proclaim the significance of heritage sites, adding labels, signposts, or other markers in a process that has witnessed the “musealisation” of place. “Experts” who

attach their own meanings to sites or objects have largely carried out these processes, not the local people or visitors who experience them. There is a paradox here, in that these organizations declare what is important on a national scale, but until recently have only rarely taken local needs or interests into consideration. This can mean that the features of the immediate environment that local people value most may not be protected, and even where they are that the associated histories or stories told are too “academic,” irrelevant or take no heed of local knowledge.

A new museological approach demands two important changes in attitude. The first of these, the realization that the museum has a role in documenting places (sites) beyond the walls of the museum as well as constructing place in its exhibitions, has been largely accepted. The second demand—community empowerment—is beginning to be met in developed, and some developing, countries. One new philosophical approach that recognizes these needs is ecomuseology, which has the potential to provide local people with a process for rescuing fragments of heritage, a building, redundant factory, a habitat, intangible heritage, or a way of life from loss or destruction, and also helps them to express a deep conviction to preserve and deepen their sense of place.

Empowerment became a key feature of ecomuseum philosophy and practice as it emerged in the late 1960s and early 1970s.^[56] Its two main proponents, Hugues de Varine and Georges Henri Rivière (1897–1985) were central to the development of new ideas about place, communities, and heritage. The first experiments with ecomuseology occurred in French Regional Natural Parks and other rural areas in the late 1960s. Later developments focused on postindustrial urban areas, most famously at Le Creusot-Montceau in Burgundy (1974).^[57] The latter established not only political, social, and regeneration ideals but cemented the concept of the “fragmented museum,” which encouraged the visitor to explore the local area by visiting several local heritage sites. This split-site approach has since become the most common feature of ecomuseums worldwide. By this time the ecomuseum had taken the notion of place, expressed as “territoire” (territory), as a cornerstone of its philosophy and industrial heritage had been identified as of particular significance, a situation that was in tune with the growing “industrial museum” movement of the 1970s.

The word “ecomusée” was devised in September 1971 by De Varine to express new museological approaches to community–heritage–place interactions. Rivière’s^[58] definition of the term ecomuseum includes many of the key concepts—local identity, territory, landscape, a sense of history, and continuity—that appear to be important in creating a sense of belonging. Perhaps the most significant features of Rivière’s definition are the repetition of the word “population” (the emphasis on communities) and the idea of the ecomuseum having “limitless diversity,” a suggestion that the ecomuseum can be anything local

people and museum professionals want it to be, and that it is a malleable concept.

One of the most interesting features of Rivière’s definition^[58] is the comment that “it is an interpretation of space—of special places in which to stop and stroll.” Here is the link to place—the ecomuseum is not limited to a building or even a museum site, but it encompasses everything within the region it refers to as its “territoire.” Here, key sites have special meaning and are integrated into the museum. Heritage is not defined, but the assumption is that it is more than just sites and material culture, encompassing memories, folklore, music, and song. At the extreme, the ecomuseum includes everything within its territory. Intangible local skills, behaviour patterns, social structure, and traditions are as much a part of the ecomuseum as the tangible evidence of landscapes, geology, wildlife, buildings and objects, and people and their domestic animals. As Van Mensch^[59] observed “it has become increasingly difficult to discern where the ‘museum’ stops and the ‘real world’ begins.”

There have been many attempts to state succinctly what an ecomuseum is. Rivard^[60] compared the traditional museum (= building + collections + experts + public) to the ecomuseum (= territory + heritage + memory + population). Varine suggested that the label “ecomuseum” was nothing more than an opportunity to run with new ideas, to be imaginative, and to initiate new ways of working.^[61] Despite the problems of definition, the flexibility of the ecomuseum model has meant that some 400 are now found worldwide, on every continent, with the recent growth in Asian countries being especially marked. Here, the processes of creating ecomuseums have been frequently linked to meeting demands for sustainable tourism, encouraging conservation, and interpretive practices of places that will ultimately benefit local people. It is this trend that led Davis^[62] to define the ecomuseum as “a community-driven museum or heritage project that aids sustainable development.” It is this link to economic development through low-level tourism that has encouraged the rapid adoption of ecomuseum practices worldwide. Now fully established in Europe, and especially France, Spain, Portugal, Italy, and Sweden, the concept is now emerging strongly in South America and especially Asia, with significant numbers created in Japan and China.

The one characteristic that appears to be common to all ecomuseums is their pride in the place that they represent. This is true whatever the nature of the ecomuseum, whether it be a rural farming community in mainland China, a scattered group of heritage sites on a Japanese peninsula, an old farm settlement in Brittany, or abandoned terraces in northern Italy. This pride is expressed in a variety of ways. It can be seen in the careful design of an exhibition, in the sheer pleasure people take in performing local music and dance, the pride in demonstrating weaving skills, or delivering bold and imaginative interpretation. Ecomuseums encourage dialogue with

local people as well as inviting visitors to explore their territory, which can only promote a better understanding of sense of place and local identity.

CONCLUSION

Museums have an affinity with places and their peoples. The origins of public museums in the nineteenth century are often associated with “local” or “civic” pride, the museum being perceived as a venue to reflect on the natural and cultural characteristics of a place and the achievements of its people. However, in the twenty-first century the rapidly changing nature of places—in terms, for example, of their spatial characteristics, ethnicities, and cultures—require museums to adapt to new needs and find different techniques—and new models—to engage with and represent changing local communities, and to construct images of place that meet local demands.

Abstract

This entry gives an overview of the area of music information retrieval. More specifically, it focuses on what has been done for retrieving polyphonic musical documents both in symbolic and audio forms. It also describes research efforts to combine symbolic-based and audio-based approaches.

INTRODUCTION

The spread of the Internet and the creation of the World Wide Web have offered exciting real-world problems for existing and novel theories and methods. Among the large amount of digital documents publicly available, there is a large number of musical documents, in various formats, that should be retrievable in musically pertinent and user-friendly ways.

This entry focuses on content-based techniques, as opposed to the text-based methods, developed for retrieving music from large databases of polyphonic music. In a typical setting the query pattern to be searched for is a short musical excerpt that can be given, e.g., by humming or playing an instrument, or by recording a snippet from a sound recording. In this entry, we divide the techniques in two categories depending on whether they are based on symbolic or audio representation. In general, the symbolic methods are appropriate for a *query-by-humming* application, where an occurrence of a query forms only some portion of the whole polyphonic structure of the matching part in the database. The audio methods are used for *query-by-example* applications, where the query constitutes a possibly distorted snippet taken from the underlying database.

The symbolic techniques developed for content-based music retrieval are based either on string or on geometric representation. The “Symbolic Techniques” section gives an overview on techniques and results that are obtained by using these frameworks. In the section “Audio Techniques,” we provide a survey of different content-based problems using audio representations that have been proposed. The survey is structured based on the type of query used, the information extracted and the specificity of the desired results. Finally in the section “Bridging Symbolic and Audio Content-Based Music Retrieval,” we conclude the entry by some ideas on how to bridge the gap between the symbolic and audio techniques.

SYMBOLIC TECHNIQUES

Symbolic music representations, such as the Western Common Music Notation (CMN) or Music Instrument Digital Interface (MIDI), are most often used for storage purposes: they include detailed information for artists or, in the case of MIDI for musical instruments, how to perform the stored music. Although performances differ from each other, the listener still perceives them as the same musical works. This justifies the use of symbolic representations for content-based music retrieval purposes. The advantage of performing retrieval in the syntax level (i.e., using a symbolic representation as opposed to audio) is the possibility to search for occurrences that are embedded in the music structure, such as a melody line in a polyphonic orchestration—the occurrence may even be distributed among several instruments of the orchestration.

Choosing the representation. There are several important, intrinsic features of music and the application that need to be taken into account to have effective retrieval results, the most important being:

1. the inherent polyphony of real-world music,
2. location invariance to allow occurrences to reside anywhere in the database, not just in incipits (the “opening line” of the music; usually the first four bars of the melody),
3. transposition invariance to allow matching music in different keys,
4. time scaling invariance to allow matching music in different tempi, and
5. tolerance to “noise” caused by various sources (the database may contain unexpected musical embellishments, a conversion process may have caused errors, the hummed/played query pattern contains inaccuracies).

Together these five features form a complex problem field and they all have to be considered already when choosing a suitable representation.

Previously, the symbolic representations used for content-based music retrieval have been based either on string^[1–4] or geometric representations.^[5–10] Of the five aforementioned properties, the first one has the strongest impact on choosing an appropriate representation. As opposed to monophonic music, which is relatively naturally representable by using string representation, casting polyphonic music to linear strings^[11–14] is often not effective.^[15] However, string matching has been adopted to some restricted cases, as discussed below. When using the string matching framework, the properties (3) and (4) are dealt with at the representational level, the remaining ones by the methods solving the specific problems.

The geometric representations, on the other hand, accommodate equally and naturally to both monophonic and polyphonic music. This discrimination has led most of the recent studies on symbolic content-based music retrieval to focus on the geometric representations. With the geometric framework the properties (2–5) are typically dealt with the methods solving the problems.

Using String Matching Framework

Problem definition

When using the string matching framework, the polyphonic content-based music retrieval problem is casted to a slightly modified string matching problem. In this case the usual setting is such that the pattern to be searched for is monophonic while the database to be searched is polyphonic. To this end, let us represent both the musical pattern $P = P_1, \dots, P_m$ and the database $T = T_1, \dots, T_n$ as strings of sets of integers. Thus, in a string S (corresponding either to P or T) each S_i models a chord and is formally a subset of an integer alphabet Σ . Let us denote by q the size of the largest chord in S , i.e., $q = \max \{|S_i| \mid 1 \leq i \leq m, n\}$. The polyphonic structure may consist of K parallel monophonic *voices*. In such a case each S_i consists of pairs $\langle k, h \rangle_i \in K \times \Sigma$ in order to be able to track the voicing information. Naturally, if $q = 1$, S is monophonic; otherwise it is polyphonic. Each S_i thus corresponds to a chord of notes, and is comprised of notes having their onsets simultaneously. This representation is also known as *onset-based representation*.^[15]

The content-based music information retrieval (MIR) problem is as follows. Given a long database $T = T_1, \dots, T_n$ and a relatively short music query pattern $P = P_1, \dots, P_m$, the task is to find all locations in T where P occurs. Here an occurrence might mean an exact, transposed, or approximate occurrence.

We define that there is an *exact occurrence* of P at position j , if $P_i \in T_{j+i-1}$ holds for $i = 1, \dots, m$. Furthermore, there is a *transposition invariant occurrence* of P at position j , if there is an integer d such that each $(P_i + d) \in T_{j+i-1}$.

When both P and T are monophonic, an exact and a transposition invariant occurrence means that $P_i = T_{j+i-1}$ and $(P_i + d) = T_{j+i-1}$ for each i , respectively. A k approximate occurrence of P is found if there is a subsequence P' of T , such that P' can be obtained from P by using k or fewer editing operations. An *approximate transposition invariant occurrence* is defined accordingly.

Results

When dealing with the polyphonic content-based music retrieval problem, in some limited cases it may suffice to heuristically reduce the polyphonic music structure in a monophonic one and then apply classical string matching algorithms. See, for instance Blackburn and DeRoure^[16] and Uitdenbogerd and Zobel^[17] for such reduction heuristics. The power of the onset-based representation becomes evident when searching for *distributed occurrences* of the pattern. In such a case the pattern appears in consecutive positions within the database but may jump across the voices (or the voicing information is simply absent).

If transposition invariance is not needed the edit distance framework can be used in a straightforward manner.^[11,12,18] The combinatorial explosion in the transposition invariant case can be avoided by chopping the possibilities in n -grams (strings of length n).^[19] When the degree of polyphony is high, however, this may prove not to be an efficient solution because of the large number of generated n -grams. Another possibility is to split the pattern to bare intervals that are searched individually.^[13] This requires a two-pronged search: the candidates found in the first phase have to be examined in another phase to discard discontinuous patterns (the subsequent interval does not begin in the note where the former ends). When the voicing information is available, one can also look for a transposition invariant occurrence that minimizes the number of jumps across the voices.^[14]

Using Geometric Framework

Problem definition

Let us now introduce the geometric framework and consider the content-based music retrieval problems as point pattern matching ones. The points are real values in a d -dimensional real space $\mathbb{R}^d$; at times the space needs to be discretized to the integer space $\mathbb{Z}^d$ for efficiency purposes.^[5,7] In a typical case, music is represented by using two dimensions: one (horizontal) dimension represents the note *onset time* (i.e., when the associated note is to be invoked), the other (vertical) gives the *pitch* (i.e., the perceived height of the note) information. To consider the note durations, several extensions to this basic point setting have been suggested^[6,9,20] (see below).

In this way, the symbolic content-based music retrieval problems can be seen as special cases of point pattern

matching (an excellent tutorial to point pattern matching can be found in Mäkinen and Ukkonen).^[21] Let us consider this more formally. Given two point sets P and T , where typically $|P| \ll |T|$, both being finite subsets of $\mathbb{R}^d$ ($\mathbb{Z}^d$), the general task is to search for pairs (f, τ) where f is a transformation ($f \in F$) and $\tau \subset T$, such that $f(P)$ matches τ . To take care of the properties (2) and (3) (cf. above), the set of allowed transformations includes *translations*, denoted by F_t , where a constant vector is added to each point in P . Time scaling invariance (property (4)) is obtained by including *scales*, denoted by F_s , in which case distances to a common origin are multiplied by a constant. Depending on the application, a *match* may be exact or approximate; in the latter case an appropriate similarity measure needs to be selected. Please note that by definition, as opposite to the string matching case, an exact match allows “extra intervening” elements in T .

The most typical problems are exact point pattern matching and largest common pointset matching under translations. In *exact point pattern matching under translations* the quest is to find $f \in F_t$ such that $f(P) \subset T$. The straightforward way to include approximation in this is to allow a minimum number of unmatched points of P . To that end, the *largest common pointset matching under translations* looks for the largest $\tau \in T$ where $\tau \subset f(P)$ for some $f \in F_t$. The respective problems including scalings are defined analogously.

Results

In the following we assume that P and T are lexicographically ordered. (Let $(a,b), (a',b') \in \mathbb{R}^2$. In a *lexicographic order* vector $(a,b) \leq (a',b')$ if and only if $a < a'$ or $(a = a' \text{ and } b \leq b')$.) If that is not the case, they can be ordered in $O(|P| \log |P|)$ time and $O(|T| \log |T|)$ time, respectively. Moreover, recall that typically $|P| \ll |T|$.

Matching under translations. The exact point pattern matching problem under translations is solvable in $O(|P||T|)$ time and $O(|P|)$ working space.^[6] However, the solution has an expected running time of $O(|T|)$. For deterministic point pattern matching algorithms quadratic running times seem to be the lower bound.

THEOREM 1. [8] THE LARGEST COMMON POINTSET PROBLEM UNDER TRANSLATIONS IS 3SUM-HARD.

If we assume that $|T| = n$ and $|P| = \Theta(|T|)$, according to Theorem 1 an $o(|P||T|)$ time algorithm for largest common pointset would mean that there is an $o(n^2)$ algorithm for the 3SUM problem, which would be an unexpected theoretic breakthrough. (Given n numbers, the 3SUM problem is to find whether there are three numbers a , b , and c among them for which $a + b + c = 0$ holds.)

A straightforward algorithm solving the largest point pattern matching under translations runs in $O(|P||T| \log |P|$

$|T|)$ time.^[22] The algorithm calculates translation vectors from each point in the pattern P to each point in T . The translations are subsequently sorted in order to find the translation giving the maximal occurrence. With a better sorting routine the running time can be improved to $O(|P||T| \log |P|)$.^[6]

To date, no deterministic algorithm is known to solve the problem in a quadratic time. It may be that the largest point pattern matching under translations is also SORTING $X + Y$ -hard, in which case Ukkonen et al.’s algorithm may already be an optimal solution. (Given two sets X and Y of n numbers, the SORTING $X + Y$ problem is to sort the set $X + Y = \{x + y \mid x \in X, y \in Y\}$.)

By accepting that some of the true occurrences may not be found, faster solutions are obtainable. To this end one can either use subquadratic time approximation algorithms,^[8,9] or a solution based on discretized values and an indexing schema similar to inverted files used for natural language information retrieval.^[5]

Indexing. Exact solutions based on indexing face two major problems; let us assume an index T for T that is built in time $f(n)$. First, Theorem 1 implies that it is 3SUM-hard to create largest common pointset queries using T , working in $g(m)$ time and holding $f(n) + g(m) = o(n^2)$. Second, the number of the possible translation vectors is exponential in the length of T and, therefore, a total index would also require exponential space.

In addition to the inverted file approach, recently two more indexing schemes have been proposed. The first uses a *metric index* working under earth moving distance.^[20] However, it seems difficult with this approach to support translations or partial matching with polyphony. Another method is to use a sparse index and a statistical filtering approach to search for promising areas in T . This approach relies heavily on the power of filtration but seems to be several orders of magnitude faster than the online (nonindexing) algorithms, both in the exact point pattern matching and in the largest common pointset problem.^[10]

Note durations. There are several suggestions on how to equip symbolic representations with note durations. A natural idea is to replace the points (representing the note onsets) with horizontal line segments, where the length of the segment represents the duration of the corresponding note.^[6] Then the task becomes to search for a translation so that the segment patterns, representing P and T , intersect as much as possible. Interestingly enough, this modified problem is solvable in $O(|P||T| \log(|P||T|))$ time, and if reduced to integer space, in $O(|P||T| \log |P|)$ time.^[6] The space reduction also enables the use of a more general distance function considering consonance/dissonance aspects of the music in hand.^[17] Other possibilities include the use of earth moving distance when the durations are represented as the weight of the points^[20] or the use of a third dimension to represent the durational information.^[9]

Matching under translations and scaling. For the moment, it has not been widely studied how to have both translation and scaling invariance at the same time. The problem in combining these two invariances is due to that the former is an additive, while the latter is a multiplicative property. Recall that the translation invariance actually captures two features: transposition and location invariances. The obvious way to achieve scaling invariance would be the use of a logarithmic encoding of the time axis. That way, however, only occurrences starting at the origin chosen for the logarithmic scale would be found thus losing the location invariance.

A naïve solution for solving largest common pointset problem under translations and scaling works in time $O(|P|^3 |T|^3)$. First, the translation vectors are calculated, in a lexicographical order, from each point in the pattern to each point in the database. This gives $|P|$ increasing sequences of vectors (pairs of real values) each of length $|T|$. Then, each possible time scaling value is selected by choosing two vectors from two distinct sequences; there are $O(|P|^2 |T|^2)$ possibilities in this choice. For each time scaling value, the maximum co-occurrence between pattern and database needs to be determined. This can be done by checking whether each of the remaining $|P| - 2$ sequences (each containing $|T|$ vectors) includes a vector that accords with the chosen scaling factor. This is feasible in $O(|P||T|)$ time. These found candidates are to be verified by checking that the associated pitch intervals also match.

In order to avoid the high polynomials in the running time, it has been suggested to consider only those scalings that appear within a window whose width is chosen independently of the size of P and T .^[9]

AUDIO TECHNIQUES

A wide variety of different retrieval scenarios have been explored using audio-based techniques. In many cases they can be formulated as “query-by-example” applications in which the user provides a possibly distorted snippet and looks for similar music pieces in a large collection. Even for the cases where the “query-by-example” view is not a perfect fit it is a reasonable approximation. For example, genre or style classification can be formulated as a retrieval problem where given a piece of music or a genre label the system returns other pieces in the same genre or style. In addition even in the cases of systems with no notion of a query such as audio-based music browsing systems based on exploration many of the underlying techniques and algorithms are the same.

A rough taxonomy of audio-based MIR systems can be created along the following major “dimensions”: query type, extracted information, and specificity. Although for presentation purposes we describe these various stages and types of information separately, successful MIR systems typically utilize multiple of these stages and

representations. The citations provided are mainly representative of existing research and its diversity rather than being an exhaustive list.

Query Type

Probably the most common type of query is a piece of music in audio format (query-by-example). The goal of the MIR system is to retrieve other pieces of music from a large collections that sound “similar” to the example query. This problem is typically formulated as a nearest neighbor problem between audio content representations which are described in more detail below. Other query possibilities are based on metadata such as genre,^[23] style,^[24] mood,^[25] or artist name.^[26] These problems are typically formulated as classification problems and solved using a supervised learning approach. In such an approach the MIR system is “trained” to classify music pieces it has not encountered before by analyzing music pieces that have been labeled by a human. This is done in order to create statistical models that can predict the correct label with high accuracy for data that has not been encountered before. A variety of such “classifiers” have been proposed including Gaussian mixture models, decision trees, artificial neural networks (ANNs), and support vector machines (SVMs). More details can be found in textbook such as Theodoridis and Koutroumbas.^[27]

Although not as explored as the previous two approaches to queries another interesting possibility is for the user to “perform” some aspect of the desired returned results. Examples of such “performed” queries include beat-boxing,^[28] humming,^[29,30] singing,^[30] tempo by tapping, or even matching the retrieved music to the speed of jogging and more generally specific exercise goals.^[31]

Representations and Extracted Information

A variety of different sources of information can be used as the basis for creating audio music retrieval systems. To some extent the traditional musical aspects of melody, harmony, rhythm, and instrumentation have inspired similar types of audio analysis. The most direct modeling is through sequences of feature vectors that statistically represent the time varying timbral characteristics of a music piece. Frequently features proposed for speech recognition such as the Mel-Frequency Cepstral Coefficients (MFCCs)^[32] are utilized. MFCCs summarize spectral information (the energy distribution of different frequencies) by taking into account the characteristics of the human auditory system. Such features depend on the instrumentation of a piece, how the timbral “texture” changes over time as well as how humans perceive this information.

In other cases, for example in cover song identification or automatic chord detection, it is desired to have a representation that is related to the pitch content of the music

rather than the specifics of the instruments and voices that are playing. Although a full music score generated by an automatic transcriptive system could be used, unfortunately current transcription technology is not robust enough to be used reliably. Instead the most common pitch content representation is the Pitch and Pitch Class Profile (other alternative names used in literature are pitch histograms and chroma vectors). The pitch profile measures the occurrence of specific discrete musical pitches in a music segment and the pitch class profile considers all octaves equivalent essentially folding the pitch profile into 12 pitch classes. The pitch profile and pitch class profile are strongly related to the underlying harmony of the music piece. For example, a music segment in C major is expected to have many occurrences of the discrete pitch classes C, E, and G that form the C major chord.

Automatically extracting information related to rhythm is also an important component of audio MIR systems and has been an active area of research for over 20 years. A number of different subproblems within this area have been identified and explored. The most basic approach is finding the average tempo of the entire recording which can be defined as the frequency with which a human would tap their foot while listening to the same piece of music. The more difficult task of beat tracking consists of estimating time-varying tempo (frequency) as well as the locations in time of each beat (phase). Rhythmic information is hierarchical in nature and tempo is only one level of the hierarchy. Other levels frequently used and estimated by audio MIR systems are tatum (defined as the shortest commonly occurring time interval), beat or tactus (the preferred human tapping tempo), and bar or measure. For some MIR applications such as automatic classification it is possible to use a representation that provides a “salience” value for every possible tempo—e.g., the beat histograms described in Lu, Liu, and Zhang.^[23]

Beat analysis approaches can be characterized in different ways. The first and most important distinction is by the type of input: most of the earlier beat tracking algorithms used a symbolic representation while audio signals have been used more recently. Symbolic algorithms can still be utilized with audio signals provided an intermediate transcription step is performed—typically audio onset detection. Another major distinction between the algorithms is the broad approach used which includes rule-based, autocorrelative, oscillating filters, histogramming, multiple agent, and probabilistic. A good overview of these approaches can be found in Chapter 4 of Klapuri and Davy.^[33]

In many modern pop and rock recordings each instrument is recorded separately and the final mix is created by a recording producer/engineer(s) who among other transformations add effects such as reverb or filtering and spatialize individual tracks using stereo panning cues. Information about this production process can be reverse-engineered from the recording and although not strictly

musical in the traditional sense can be used to build more effective MIR systems. For example, the amount of stereo panning and placement of sources remains constant in older recordings that tried to reproduce live performances compared to more recent recordings that would be almost impossible to realize in a live setting. Stereo panning features have recently been used for audio classification.^[34]

Specificity

Given a particular query as well as a representation that captures relevant musical content information the user expects to retrieve a set of results that are “similar” in some way to the original query. A variety of different “similarities” have been explored with varying degrees of specificity. The most specific type of retrieval is audio fingerprinting where the goal is to return other instances of the exact same recording possibly subject to noise, minor edits (such as hand clapping removal), and audio compression.^[35] Audio fingerprinting can be used for discovering copyright violations as well as associating metadata with music pieces. Remixes also correspond to the same underlying recorded performance, however, with the addition of extra musical materials such as drum loops and beats. In cover song identification the goal is to find other recordings of the same song that are performed by different musicians and instrumentation.^[36] Content-based features for cover song identification must capture higher level musical constructs such as chord progressions and not be sensitive to instrumentation changes. Pitch and pitch class profiles are frequently used for this purpose. Artist,^[24] album and genre similarity^[23] although to some extent artificial tasks have the advantage that it is relatively straightforward to obtain ground-truth using existing metadata associated with files and therefore provide qualitative comparisons between different feature sets for describing audio content.

Specificity also relates to the amount of relevant results returned by the system which has implications about the methods used for matching. High-specificity results typically only return few relevant objects and therefore typically require calculating some kind of similarity or matching function between the query and all items in the collection. For low-specificity queries such as, e.g., based on a genre label the number of retrieved objects is typically much larger and therefore amendable to a different type of approach. When there is sufficient label data supervised machine learning techniques can be used to “train” statistical models of the data that can directly “classify” a music piece with a discrete category. Retrieval can then be more efficiently performed by randomly selecting pieces and returning as relevant only the ones that have the correctly assigned label avoiding full comparisons of the query with the entire collection.

Evaluation

Music information retrieval is a new growing research area and one of the major challenges that researchers have to face is evaluation. A lot of the early work in MIR and still a large part of existing work is performed with in-house datasets which makes systematic comparison of different approaches and algorithms impossible. Since 2005 MIREX (the MIR Evaluation eXchange) http://www.music-ir.org/mirex2007/index.php/Main_Page has been an effort to address this problem and provide comparisons and evaluations on common datasets. It is a community-based formal evaluation framework coordinated and managed by the International Music Information Retrieval Systems Evaluation Laboratory (IMIRSEL) at the University of Illinois at Urbana-Champaign (UIUC). Every year based on interest by the community a set of different tasks are proposed and research groups around the world submit their algorithms for comparative evaluation. One of the challenges with MIREX is that the datasets used are not provided to the participants and therefore all submitted algorithms must be executed at UIUC. This to some extent also prevents “overfitting” of submitted systems to the particular data collection. Browsing the results for each task is a great way to see what the current state of the art is and which groups are active in each task. There are multiple metrics that can be used to evaluate different systems even for the same task. In order to provide a rough picture of the current state of the art we provide representative results of the “best” performing systems for some of the MIREX audio-based tasks: genre classification 68.29% (7000 30-sec clips, 10 genres, MIREX2007), audio mood classification 61.50% (600 30-sec clips, 5 moods, MIREX2007), and audio artist identification 48.14% (30-sec clips, x artists, MIREX2007). All these results show percentage of clips correctly classified using a threefold cross-validation scheme where one-third of the data is used for testing and two-thirds for training and the process is repeated three times. Other results include audio music similarity 0.568 (100 random queries from 7000 songs, evaluated by human graders with a fine score between 0 and 10, score is the normalized sum of fine-grained human similarity decisions, MIREX 2007) and audio tempo extraction 94.29% (percentage of at least one tempo correct, MIREX 2006).

User Interfaces

Ultimately any MIR system needs to be used by humans. Music listening is a personal, subjective, enjoyable experience which automation should enhance and support. Therefore, the interaction with the user is a critical and essential component of MIR research that has been gaining importance as the field matures. One of the interesting directions in this area is content- and context-aware user interfaces that rely on automatic audio analysis

techniques to inform the visual presentation of music collections. Such interfaces typically employ content-based audio feature extraction as described previously followed by dimensionality/visualization techniques that map the extracted features into visual attributes or positions of objects. Self-organized maps (SOM) are used in the Islands of Music system to map audio feature vectors to positions in a two-dimensional grid which is colored using a map metaphor.^[37] Musicream utilizes principal component analysis (PCA) to assign colors to disks that represent individual music pieces and to adjust the playlist composition by using a water tap metaphor.^[38]

BRIDGING SYMBOLIC AND AUDIO CONTENT-BASED MUSIC RETRIEVAL

The obvious possibility for bridging symbolic and audio content-based music retrieval is to use an automatic polyphonic music transcription method for extracting a symbolic representation from an audio signal, and then to apply some of the methods described in the section “Symbolic Techniques.” Nevertheless, automatic polyphonic transcription is a hard technical problem for which there is no current general-purpose and reliable solution, although there has been remarkable progress in this direction.^[33]

In some cases it is possible to combine symbolic and audio content-based music retrieval approaches without requiring a full music transcription system. For example, it is possible to use the monophonic reduction (recall from the section “Using String Matching Framework”) in order to use symbolic queries for audio databases^[39] or to retrieve a symbolic score from a score collection by using a polyphonic audio query.^[40] More generally, the polyphonic audio-score alignment can be used to discover the respective parts of an audio signal and a score.^[41,42] An *off-line* application for such an alignment is in the back-end of a query-by-humming system: the back-end is needed in order to playback the part of an audio file that corresponds to the found occurrence, in a symbolic music file, of a hummed query. *Online* audio-score alignment is needed in computer accompaniment.^[43]

Abstract

This entry explores the major aspects of music librarianship beginning with a review of the core literature, types of music libraries, professional organizations, and music librarianship as a career. The general areas of acquisition, cataloging, classification, reference, and preservation are examined as they relate to the unique needs of music. Future challenges to the profession are summarized.

DEFINITION

Music librarianship is a specialization of librarianship that involves the acquisition, cataloging, and preservation of music materials in audio, visual, print, and digital formats and the provision of instructional and reference services to the users of these materials.

LITERATURE

In 1893, James Duff Brown^[1] wrote the first manual describing the organization of a music library. Books and collections of essays about music librarianship offering an historical perspective include McColvin,^[2] Bryant,^[3] McColvin and Reeves,^[4] Redfern,^[5,6] Jones,^[7] and Turbet^[8] written from the British point of view and Wallace,^[9] Hill,^[10] Bradley,^[11] Mann,^[12] Ochs,^[13] and Cassaro^[14] viewed from the American perspective. Additionally, Bradley^[15] compiled a collection of seminal articles published about music librarianship up until 1973. Timely essays summarizing the state of the profession appeared in *Notes*, the official journal of the Music Library Association, by Watanabe (1981),^[16] by Davidson (1993),^[17] and by contributors in the field in a special millennial issue.^[18] In *American Music Librarianship: a Biographical and Historical Survey*,^[19] Bradley acknowledged the pioneers who built collections, devised classifications, and developed cataloging codes. She later documented the literature of the field in her exhaustive bibliography *American Music Librarianship: a Research and Information Guide*.^[20]

TYPES OF MUSIC LIBRARIES

Academic Libraries

Academic music libraries primarily serve students, faculty, and visiting scholars. Collections are driven by the evolving curriculum of the institution and are important resources supporting its educational mission. Such collections tend to be interdisciplinary in scope and are augmented by musical archives of importance to the institution and the locale. Critical editions, study scores, sound and visual recordings, and monographs and periodicals on music-related topics form the basis of these scholarly collections. Depending on the curriculum, performing editions with parts are often well-represented in the collection.

Academic music libraries employ music librarians, frequently with advanced degrees in music, to administer the collection, develop and catalog it, provide instruction, and answer reference questions. The work of the music librarians is usually supported by library and/or student assistants.

Academic music collections may be incorporated within a general academic library or exist as a separate branch library. Often music collections were initiated in music departments and later incorporated into the administrative structure of the institution's academic library.

Research Libraries

Research libraries are administered by an organization, founder, or foundation. As a result, these collections may be more narrowly focused in accordance with the mission of the supporting body than their counterparts in

academia. Examples of research library collections may be found worldwide in societies, foundations, museums, and church, monastery, or other spiritual organizations, for example, the Moravian Music Foundation (the United States), the International Library of African Music (South Africa), Internationale Stiftung Mozarteum Bibliotheca Mozartiana (Austria), English Folk Dance and Song Society, Vaughan Williams Memorial Library (the United Kingdom), and Biblioteca Apostolica Vaticana (Italy). Staffing of these collections ranges widely. Research music libraries may employ music librarians with advanced degrees or expertise in specific areas of music. However, small collections may be administered by knowledgeable volunteers.

Conservatory Libraries

Conservatory libraries, at institutions such as the Curtis Institute of Music (the United States), Royal College of Music (the United Kingdom), and Sibelius Academy (Finland), serve students, faculty, and visiting artists. Similar to the academic library, their collections are driven by curricula; however, the emphasis is generally on performance and pedagogy. Performing editions with parts, orchestral excerpts, sound and visual recordings, and monographs on performance issues are augmented with the basic resources found in academic libraries. Conservatory libraries may also perform an archival role relating to the institution or to artists of local interest. Conservatory music libraries hire music librarians to administer the collection, develop and catalog it, provide access and bibliographic instruction, and answer reference questions.

Public Libraries

Public library music collections are shaped by the size and resources of the community they serve as well as the significance of local historical music events. They are funded by local government and most contain some music-related monographs and small popular music audio/visual collections. However, large public library collections such as those found in major cities are similar to research collections. While public libraries may maintain archival collections of local music history, the primary aim of the library is to circulate materials and provide access to members of the community. Public libraries with large music collections employ several music librarians. In smaller public libraries, the tasks of collection development, cataloging, and reference may fall to those librarians who have an interest in the subject.

Music Information Centres

Music Information Centres are national organizations that collect, document, and promote the music of the supporting country. Services are provided to anyone

worldwide with an interest in the music of the country. Collections include scores, recordings, and biographical and research materials. In addition to administration, collection development, cataloging, and reference, Music Information Centres are charged with promoting the music of their country through various activities. Since 1939, the American Music Center has served this purpose for the United States.

National Libraries

National libraries are generally responsible for “acquiring, cataloguing, and maintaining copies of the national bibliographic output and preparing the national bibliography.”^[21] These library collections combine characteristics of public and research libraries and Music Information Centres. Like public libraries, national libraries are funded by a government and provide services to its citizens. However, national music libraries are broader in their collection scope than most public libraries and may include scores, sound and visual recordings, and monographs and periodicals on music-related topics. Similar to Music Information Centres, they collect and promote the music of their country. Often they are required by legislation to serve as a repository for copyrighting newly published music and many also set cataloging and other policies for libraries in their country. Music collections in national libraries are staffed by music librarians. Some of the many important national libraries with substantial music collections include: the British Library (the United Kingdom), Bibliothèque Nationale de France (France), Bayerische Staatsbibliothek (Germany), Oesterreichische Nationalbibliothek (Austria), Biblioteka Narodowa (Poland), Rossiyskaya Gosudarstvennaya Biblioteka (Russia), and the National Diet Library (Japan). Though often considered a national library, the Library of Congress (the United States) was created to serve the members of Congress.

Performance Libraries

The purpose of a performance library is to meet the specialized needs of performers and performing organizations. These library collections include few of the music reference and sound and visual recordings found in other types of music libraries. In these libraries, the music librarian is responsible for obtaining the music needed for performance each season through purchase or rental, organizing and maintaining parts acquired by the organization, and marking parts with directions for performance as required by the conductor of the work. Librarians from many of these organizations are served by a professional society, the Major Orchestral Librarians Association (MOLA).

Because of its global lending policy and extensive holdings, the Edwin A. Fleisher Collection of Orchestral

Music, at the Free Library of Philadelphia, is the world's largest lending library of orchestral performance material.

Media and Broadcast Libraries

Significant changes have taken place in the collections of radio and broadcasting station libraries. In the United States, until recently, radio stations maintained large collections of physical recordings. With the rise of Internet radio stations, digitized collections are being amassed for streaming. Many traditional stations are digitizing recordings to offer content via both Internet and terrestrial radio.

In Europe, radio broadcast libraries, such as the British Broadcasting Corporation Music Library, traditionally provided scores for broadcast performances. Over time, some collections changed their focus as has Radio France, Documentation Musicale which originally provided performance scores for its orchestra, Orchestre National. It now acts as a national documentation center promoting contemporary music. In the past, Sveriges Radio Förvaltning, Musikbiblioteket commissioned works for radio and television performance, thus it contains autograph manuscripts of Swedish composers in addition to other performance scores.

PROFESSIONAL ORGANIZATIONS

IAML: International Association of Music Libraries, Archives, and Documentation Centres (<http://www.iaml.info>)

Established in 1951, IAML provides an international forum for music libraries, archives, and documentation centers with an interest in the collection, preservation, access, and dissemination of musical sources. Open to individuals and institutions interested in the goals of the association, this trilingual organization utilizes professional and national branches, subject commissions, committees, and working groups to accomplish its aims. Institutional and individual members number approximately 2200. National branches support IAML at the local (country) level. Communication is facilitated by the IAML-L listserv and the journal of the organization, *Fontes Artis Musicae*, published in English, French, and German. IAML holds a major annual conference, hosted in a different country, to encourage member participation.

IAMIC: International Association of Music Information Centres (<http://www.iamic.net>)

Since 1986, IAMIC has served as an international organization for the 41 Music Information Centres that make up its membership. IAMIC fosters the sharing of resources and collaborative projects to further the aims of the association. Recent projects include the *2009 IAMIC Annual*

List: a "reference for performers seeking to expand their new music repertoire."^[22] Communication is provided via *IAMIC News* on the IAMIC website. Like IAML, IAMIC's annual conferences are held in different countries to allow equitable opportunities for attendance.

MLA: Music Library Association (<http://www.musiclibraryassoc.org>)

Founded in 1931, MLA is a professional organization "devoted to music librarianship and all aspects of music materials in libraries."^[23] MLA's over 2000 members are primarily music librarians from the United States and Canada; however, membership is open to all institutions and individuals, regardless of professional status, who support the work of the association. MLA is composed of committees, roundtables, and interest groups which work to further the goals of the association. Regional chapters support MLA on the local level. Communication is promoted through the listserv MLA-L, an online newsletter, and the organization's quarterly journal, *Notes*. MLA publications facilitate the work of music researchers and librarians and articulate the responsibilities and training of the music librarian. MLA holds a major annual conference, hosted in a different area of North America, for information-sharing among members.

MOLA: Major Orchestral Librarians' Association (<http://www.mola-inc.org>)

Organized in 1983, MOLA is an international association which supports the work of librarians in professional performance organizations by sharing resources and information related to the performance library arena. As of January 2009, MOLA comprised 249 member organizations, representing over 400 individual librarians, and 18 individual honorary members. Members exchange information through the association's online discussion forum and a quarterly newsletter, *Marcato*. MOLA publications facilitate the work of the members and articulate the responsibilities and training of the orchestral librarian. Annual meetings are hosted by MOLA members.

MOUG: Music OCLC Users Group (<http://www.musicoclcusers.org>)

In 1977, MOUG was formed as a task force of the Online Computer Library Center, Inc. (OCLC) to examine issues regarding OCLC's implementation of the MARC (Machine-Readable Cataloging) music format for scores and sound recordings. From its early concentration on cataloging issues, the group expanded its scope to encompass the use of OCLC products in activities such as music acquisition and reference. Communication is facilitated by the *Music OCLC Users Group Newsletter*. Membership is open to individuals and institutions that are interested in

the goals of MOUG and, as of January 2009, totaled 207 personal and 229 institutional members. Because there is much overlap in membership between MLA and MOUG, annual meetings are held together.

ARSC: Association for Recorded Sound Collections (<http://www.arsc-audio.org/index.html>)

ARSC, founded in 1966, is of particular interest to music librarians since music libraries tend to have large collections of sound recordings. ARSC's mission is to share knowledge and education about recording preservation, cataloging, history, and copyright law. The Association comprises 1072 individual and institutional members. It publishes the *ARSC Journal* and a newsletter. Annual conferences are held throughout the United States.

IASA: International Association of Sound and Audio Archives (<http://www.iasa-web.org>)

Established in 1969, IASA promotes international cooperation between libraries, archives, museums, and private collectors that preserve recorded sound and audiovisual materials. As of January 2009, interest in the work of the IASA is reflected in its 215 institutional and 180 individual memberships. Members share expertise in digitization and preserving sound in electronic formats.

The association publishes the *IASA Journal* semi-annually, and also issues an electronic bulletin, and various technical reports. Annual conferences are held in locations around the world.

CONSIDERING A CAREER IN MUSIC LIBRARIANSHIP

The ability to read musical notation coupled with a background in singing or playing a musical instrument and/or participating in a musical ensemble is essential for carrying out the responsibilities of a music librarian. For example, music catalogers must be able to read musical notation to determine the form of a piece and other identifying elements, such as key, used in descriptive cataloging; those who purchase music and provide reference service must possess knowledge of musical notation to be able to select items for a collection and to answer questions that require score identification; and those who are in charge of binding music must understand how scores and parts are used to make appropriate binding choices.

Besides a library master's degree, music librarians need a broad background in music including substantial undergraduate coursework. Often a second master's degree in music is required for those preparing to assist academic scholars. A reading knowledge of foreign languages, especially German, is invaluable in working both with the

music and the secondary literature. Knowledge of current digital resources and applications is expected, and practical experience in the profession is valued. An excellent way to gain experience for entry into the profession is through an internship in a music library as part of a library degree-related graduate program.

The Music Library Association supports mentorship activities and its website^[24] offers information about job requirements, a directory of library school offerings in music librarianship, and up-to-date details about career prospects. In April 2002, the MLA's Library School Liaison Committee drafted a report^[25] outlining the core competencies of music librarians. Published in 2004, *Careers in Music Librarianship II*^[26] offers a realistic picture of the profession through essays by professionals in the field that describe their experiences as music librarians and their assessments of career path options.

While small collections may employ only one music librarian, larger collections are better served with at least one music subject specialist and a specialized music cataloger. Thus, career advancement may only be achieved through moving on to a larger institution or taking on more varied responsibilities in the current job. Some music librarians find that managing a music library provides excellent experience for advancement to library supervisory and administrative positions. On the other hand, large academic and public libraries that employ a number of music librarians may offer opportunities for advancement within their library organizations.

DEVELOPING COLLECTIONS

Typically, music libraries contain books on music, audio and visual recordings, music scores, and specialized reference tools, indexes, and periodicals. The large collections of printed music and sound recordings make music libraries unique. Many music library collections originally focused on Western classical music and have expanded their scope to include popular genres and world music.

Acquiring music materials is challenging because they are published in multiple manifestations and recorded in different versions. In addition, the same work may be published under different titles in different languages, further complicating the issue. Traditional book vendors rarely handle music scores so acquiring these materials requires working with specialized music vendors and publishers. Book vendors may handle recordings; however, obtaining foreign and specialized labels can be challenging and require the services of knowledgeable recording vendors. Fling's *Library Acquisition of Music*^[27] presents a detailed examination of the music acquisition process and its inherent complexities. *A Basic Music Library*,^[28] now in its third edition, was written to identify what

constitutes a music library core collection of scores and recordings.

Scores

Music librarians acquire scores in different manifestations for different purposes. As Krummel observed, “Musical documents are physically distinctive for reasons which are essentially musical” (p. 327).^[29] Scores are published in different formats to meet users’ needs. For example, in the nineteenth century a market developed for scores to be used by concertgoers, who wanted scores to follow while listening. To be portable full scores were published in a reduced size that could easily slip into a pocket. Today, these scores are referred to as miniature, pocket, or study scores and are often used by students in analyzing music.

Likewise, the demand of musicians for scores to study and perform resulted in the publication of piano-vocal scores, also called vocal scores. Piano-vocal scores feature the orchestral music reduced or arranged for piano while maintaining the original vocal parts. These types of scores can be used by vocalists to rehearse their parts without requiring the full instrumental accompaniment.

Those interested in performance practice seek historical/critical editions of scores prepared from an in-depth examination of all known primary sources. These scores present the most authoritative versions of a musical work as scholars in the field have determined. A critical report, detailing the editorial practices, identifying the autograph and/or copyist’s manuscripts consulted, and outlining research issues, often accompanies each volume. Music librarians may spend a good portion of their acquisition budget on standing orders to obtain these scholarly critical editions of music.

Scholars want to consult a composer’s manuscripts, sketches, and the earliest printed editions of music to determine a composer’s intentions. When original materials are unavailable facsimiles are sought. Researchers also seek access to modern scholarly editions that reflect current scholarship.

Performers who use a music library may range in skill from beginners to professionals. For the less-skilled amateurs simplified editions, in which the composition has been reduced to the basic thematic line and an easy accompaniment, are requested. Skilled musicians look for scores reproduced with sensitivity to the intentions of the composer that do not dictate performance practice through editorial accretions. Modern publishers use the term *Urtext*, “original text,” for performing editions that attempt to distinguish editorial markings from those of the composer. Editorial practices used in producing *Urtext* editions vary by publisher. Performing editions may include indications of fingering, bowing, phrasing, tempo, and articulation markings not found in the composer’s manuscript.

Some libraries collect octavo and sheet music. The term “octavo” originates from the size of the paper folded into eights and is the size commonly used in publishing choral music. Sheet music is printed on large unbound sheets of paper and is the format commonly used for popular music. The late nineteenth and early twentieth centuries witnessed the heyday of sheet music publishing. Sheet music is of historical interest for its song texts and illustrative covers that document events and offer insights into the popular culture of the period.

Unique sheet music collections in the public domain, such as the *19th-Century California Sheet Music Project*,^[30] have been digitized to make the collections available for online viewing. Duke University,^[31] the University of California at Los Angeles,^[32] Johns Hopkins University,^[33] and Indiana University^[34] maintain their own sheet music websites and also make their collections accessible through the catalog of the Sheet Music Consortium. The Consortium, hosted by the UCLA Digital Library Program, works to build an open collection of digitized sheet music using the Open Archives Initiative standards.^[35] Their website facilitates searching sheet music collections from many institutions, including the Library of Congress, through a common interface.

Like digital sheet music collections, access to electronic music scores is a recent development. Begun as the Variations Project, Variations2^[36] for scores brought Indiana University to the forefront of digitizing music. The Sibley Music Library at Eastman^[37] and the Eda Kuhn Loeb Music Library at Harvard^[38] are examples of other libraries that have digitized scores in the public domain and offer access through their library websites. Collaborative websites of content-related library holdings, such as *CFEO: Chopin’s First Editions Online*,^[39] are also new developments. In 2007, the Internationale Stiftung Mozarteum, Salzburg, in cooperation with the Packard Humanities Institute, Los Altos, California, completed a groundbreaking project to digitize the *Neue Mozart Ausgabe* (W. A. Mozart’s complete works).^[40]

In the commercial arena, Alexander Street Press has been a pioneer in licensing access to copyrighted music (Boosey & Hawkes Study Scores) through their electronic database *Classical Scores Library. CD Sheet Music*, also available through ebrary, sells access to digitized older editions of scores in the public domain. Individual scores can be purchased and downloaded through a variety of vendors such as *Digital E-Print Delivery* from J. W. Pepper.

Audio and Visual Recordings

When Thomas Edison patented his phonograph in 1877, the way we listen to music changed forever. Before that time we could only hear music in live performance, but after the invention of sound recording, music could be

captured and listened to at any time and in almost any place. This invention made recordings of music a commodity that could be collected. Sound recordings eventually became just as important as scores to music libraries. In practice, music librarians strive to coordinate the audio and score titles collected to facilitate study and performance. Variant performances of the same work, sometimes in different instrumentation, are collected to allow users the opportunity to hear different interpretations.

Edison's phonograph recorded on fragile wax cylinders. The machine was purely mechanical, not needing electricity, and it was quite portable. This made it ideal for use in ethnographic fieldwork. The earliest cylinders of music recorded in this fashion were made by Jesse Walter Fewkes and date from the 1880s. Cylinders had several disadvantages. First, the maximum recording time on each cylinder was around three minutes; therefore, to record even a movement of a work could take multiple cylinders. They were better suited to recording popular songs and ethnographic examples rather than classical music. Second, cylinders were a fragile medium. They were made of wax or similar materials and were prone to breaking, sensitive to high temperatures, and wore down as they were being played. For these reasons, early music libraries generally did not establish large cylinder collections. Today most of these collections are found in ethnographic sound archives, like the American Folklife Center at the Library of Congress, the Archives of Traditional Music at Indiana University, Bloomington, and the Phonogramm-Archiv in Berlin.

In 1887, Emil Berliner invented and patented the gramophone that recorded on discs. These were less bulky and easier to store than cylinders, making sound recording collection more practical for libraries. Although early commercial 78 rpm discs played for about three minutes, the same as a cylinder recording, record players were developed where one could stack discs and play them one after another in sequence. This facilitated listening to lengthy classical works. For these reasons discs triumphed over cylinders in the war of competing formats.

Many technological advances were applied to disc recordings. These included making discs from new materials that were less heavy, bulky and fragile, using electrical microphones for recording and amplifiers for playback (adapted from radio), and an electric lathing process. Eventually discs featured microgrooves. Slowing the speed to 33 1/3 rpm increased the recording time to more than twenty minutes per side. They were called LPs (Long Playing recordings) and they soon featured significantly improved sound quality with high fidelity and stereo. The LP disc became the most widely collected sound recording medium by libraries.

In the 1930s, magnetic sound recording was developed in Germany. Two competing formats emerged: wire and magnetic tape. Early magnetic tape was backed with paper and was a fragile medium which could tear or lose its

magnetic surface. After World War II, magnetic tape continued to be developed in the United States, especially by the 3M Corporation, the makers of Scotch Tape. Their magnetic tape was made of newly invented plastics and offered a more permanent medium. Magnetic tape won over wire in the competing magnetic recording formats. In the early 1960s, the Phillips Corporation of the Netherlands developed the cassette tape which eventually became the most widely used recording medium in the world.^[41,42]

Magnetic tape also made possible the recording of video. Video recorders and players featured a rotating steel head that produced a recording of much higher quality, equivalent to a much faster tape speed. The home recording video market also had two competing formats, Betamax from Sony and VHS from JVC. VHS eventually became the standard format for home video recording, even though it was bulkier and not as technically advanced as Betamax, partially because VHS tapes could record up to six hours of video, compared to only one hour for Betamax. This longer time made possible the recording of feature-length films on a single VHS cassette.

Music libraries did not fully embrace collecting magnetic recordings, except for VHS tapes, and continued to collect LPs, since they offered higher quality audio and a permanent medium that could not be recorded over. Reel-to-reel tapes, which were more cumbersome to use than LPs, were found in professional applications such as studio recording, concert, or ethnographic field recording, and by audiophiles. Cassette tapes, and to a lesser extent 8-track tapes, were collected primarily by public libraries for their circulating audio collections.

In the late 1970s, a century after Edison's first patent, digital recording was commercially developed. The compact disc (CD) was invented jointly by Phillips and Sony. They avoided the major mistake made with the cassette tape in that CDs would be a permanent recorded medium, like LPs. During the final two decades of the twentieth century, the CD replaced the LP as the default pre-recorded music medium. The video equivalent of the CD is the digital video disc (DVD). Like the CD, the DVD was initially a playback only medium, but personal computers eventually made both the CD and DVD into recordable mediums. The February 19, 2008 announcement by Toshiba that it would no longer develop, market, or manufacture high definition DVD players and recorders, marked the triumph of Blu-ray over High Definition DVD in the fierce competition of formats for the next generation of video recordings.

Like audio recordings, commercial vendors are beginning to license access to streaming video content. Alexander Street Press markets the *Opera in Video* and *Dance in Video* databases that feature performances and video clips of interviews with artists.

No one could have anticipated the coming of the Internet revolution. This began with the development of the Personal Computer (PC) in the 1970s, and as millions of

these computers became networked, with ever increasing transmission and computing speeds, the Internet came into its own in the 1990s. The Internet made possible the easy recording and sharing of digital audio files. The Napster website gained notoriety for sharing audio files. Individuals could find literally millions of sound recordings, both legal and illegal under copyright laws, and download them onto their own personal computers. The Recording Industry Association of America (RIAA) sued Napster and won. Now Napster works with the recording industry and charges a modest fee for each digital file.

Recorded sound is progressing to the digital file. One can listen to music on computers and on portable devices, such as the iPod. Libraries have adapted to this revolution by subscribing to digital listening services, such as Napster, Rhapsody, *Classical Music Library* and *Smithsonian Global Sound* from Alexander Street Press, *DRAM* from the Anthology of Recorded Music, Inc., and *Naxos Music Library* from the Naxos Digital Services Ltd. These listening services feature hundreds of thousands of digital tracks of music, far beyond the ability of most music libraries to provide by purchasing physical recordings. Libraries subscribe annually for a fee which allows their patrons access, but not the downloading of files. Most libraries are engaged in determining the appropriate balance between ownership and access for their users and continue to purchase CDs based on the needs of their institution.

Reference Tools

The basic print bibliographies of music reference sources are Duckles,^[43] Marco,^[44] Brockman,^[45] and Foreman.^[46] Beginning in 2001, with *Grove Music Online* (now part of *Oxford Music Online*), publishers started to offer electronic access to some core music reference titles such as the *Harvard Dictionary of Music* and *Baker's Biographical Dictionary of Musicians*.

Thematic catalogs offer unique access to library collections. They authenticate a musical work by identifying it through its opening and/or major musical themes given in musical notation, referred to as *incipits*. Thematic catalogs also distinguish works by key, opus, and thematic catalog number and provide information about the composition's publication history, variant editions, and relevant bibliographic literature.

Other unique music reference tools include repertoire guides and graded lists, discographies, and song indexes. Musicians consult repertoire guides and graded lists in search of new works to perform. These sources include information about the musical characteristics of a composition and its performance difficulties, instrumentation, publisher, and performance timing. Discographies are bibliographies of sound recordings that offer information about a particular musician's recordings or document the recorded evolution of musical forms and genres. Song indexes provide access to large songbook collections

through song title, composer, subject, and the words of the song text.

Important to music research are indexes to the critical editions of composers' complete works and to the historical monuments of music. For many years Charles^[47] Heyer^[48] served as the definitive sources for this information. Subsequently, Hill and Stephens^[49] compiled an updated bibliography of the historical sets and series, collected editions, and monuments of music whose specific content is being entered into an electronic database version and hosted by a number of aggregators.

Music scholars use the *Répertoire International des Sources Musicales*, *The International Inventory of Musical Sources (RISM)*, to locate music manuscripts and early printed music, works on music theory, and libretti held in libraries, archives, monasteries, schools, and private collections. Only portions of *RISM* are available via electronic access, these being *Series A/II: Music Manuscripts After 1600* and the *U. S. Libretto Database*.^[50]

The Internet has become a major resource for music reference information.^[51] Large collections of music-related materials have been digitized and organized by individuals, organizations, and institutions, such as the music collections of the Library of Congress' *Performing Arts Reading Room*.^[52] Websites enable musicians, scholars, organizations, and libraries to promote their works and offer contact information and/or access to their collections.

Indexes and Abstracts

The basic indexes/abstracts to music periodical literature are: *The Music Index Online*, *The International Index to Music Periodicals (IIMP)*, and *Répertoire International de Littérature Musicale (RILM)*. *RILM*, "the first automated abstract journal in the humanities,"^[53] features abstracts in English and, most recently, in the language of publication for articles, *festschriften* (collections of celebratory essays), dissertations, and reviews in 140 languages. Although varying in coverage, journal databases such as *Journal Storage: the Scholarly Journal Archive (JSTOR)* and *Project Muse* provide a form of indexing through searchable full-text access to runs of music journals.

The *Retrospective Index to Music Periodicals, 1800–1950 (RIPM)*, indexes runs of music periodicals published before 1950 from around the world. Index coverage is intended to dovetail with *RILM*.^[54] This index is available in print, CD-ROM, and electronic formats. The *RIPM Online Archive of Music Periodicals* provides full-text access to the journals indexed in *RIPM*.

CATALOGING

Music catalogers follow the same rules *Anglo-American Cataloging Rules* (AACR 2 rev.) and use the same tools, for example Machine Readable Cataloging (MARC)

Records and Library of Congress Subject Headings (LCSH) as other catalogers; however, music has specialized provisions for bibliographic description and access. These specialized provisions and music cataloging guidelines are detailed in books written by Smiraglia^[55] and Weitz.^[56–58] In 2006, Smiraglia published a bibliography of literature relating to music cataloging.^[59]

Music cataloging practices are geared towards collections of Western classical music. This music exists in written form, either printed or in manuscript. It could be a score, showing all the parts of an ensemble displayed vertically, or a part showing the music performed by one member of an ensemble. Music libraries traditionally collect scores and parts up to nine parts. If a work has ten or more parts, such as a band, orchestral, or wind ensemble piece, it is usually housed in a separate performance ensemble library. Girsberger's *Manual for the Performance Library*^[60] provides guidance in how to organize ensemble libraries.

The composer has served as the primary point of access in music cataloging. This assumption dates from the mid-nineteenth century when cataloging rules were first being developed.^[61] Establishing the title of a piece of music has always been problematic because of the various languages used by publishers and composers, and because there are many generic forms in Western classical music, such as sonatas, concertos, and symphonies, with many pieces identified only by these generic titles. Thus, uniform titles become essential in music cataloging as a way to standardize variant titles and titles of generic forms. Also subject headings and in part, music classification systems largely rest on these standard musical forms. With the advent of musical sound recordings, the same cataloging conventions were applied.

Sheet music is “musical notation printed on sheets of paper that remain unattached and unbound at the time of sale” (p. 1).^[62] For years, music catalogers did not catalog sheet music because of its popular and ephemeral nature, and because there were no cataloging guidelines for sheet music. But as large sheet music collections began to be preserved and made available, cataloging became necessary. A working group of the Music Library Association developed cataloging guidelines for sheet music.^[62]

Music Uniform Titles

Uniform titles are more widely used in music cataloging than in any other cataloging context. Uniform titles make it possible to find a composition listed in one place, no matter its language, form, or physical arrangement. Music is published in various languages, so there frequently needs to be a single uniform title that draws together (collocates) the same musical work from various publishers. Also, music is frequently composed in a generic form. Uniform titles are needed to distinguish a particular generic piece from others of the same form by the same composer. Finally, since the very earliest time of music publication, music has been commonly published in

collections and anthologies. These anthologies need generic uniform titles to identify and group together collections, usually under a composer's name. Thus, music cataloging recognizes three types of uniform titles: Distinctive titles, Form titles, and Collective titles. Distinctive titles are unique titles, given by the composer, in the original language, for example Debussy's *Prelude to the Afternoon of a Faun* = [Prélude à l'après-midi d'un faune]. Form titles are used for “generic” works such as sonatas, symphonies, and songs. They follow a specific structure: [Form, instrumentation, number, key], for example Beethoven's *Pastoral Symphony* = [Symphonies, no. 6, op. 68, F major]. Collective titles are used for collections and anthologies of music, for example Bach, Johann Sebastian. *Neue Ausgabe sämtlicher Werke* = [Works].

Library catalogs that display uniform titles alphabetically under the composer's name allow users to see all manifestations of a work listed together. Electronic catalogs that allow linking to an item with the same uniform title are valuable tools to collocate, identify, and locate a specific piece of music. Music library users benefit by being aware of the way uniform titles are used to organize music. For detailed information about music uniform titles consult Koth.^[64]

Music Subject Headings

Library of Congress Subject Headings (LCSH) for music are unique because they fulfill two functions: to retrieve books about music and to retrieve the actual music itself. The headings used to find books about music are true subject headings. Those used to retrieve music could more properly be called form headings. Terms describing musical forms, such as sonatas, concertos, and symphonies, may be used in both types of music headings, those for finding information about a form, as well finding compositions in that form. Generally, if the term is in the plural, it retrieves the music itself. If it is in the singular, it retrieves books about that subject as a musical form. For example, the subject heading “Concertos” will retrieve scores and recordings of concertos, while “Concerto” will retrieve books about the concerto. This works for most musical forms; however, one exception is “Songs.” There is no singular subject heading “Song” for books about this musical form. The heading “Songs—History and criticism” is used.

All the music subject headings from the LCSH (to 1997) have been gathered in a single volume. For further study, this work includes an excellent seventy-five page introduction by Young about the workings of music subject headings.^[65]

The Future of Music Cataloging

Cataloging is at the very beginning of a new age. As international committees attempted to update the AACR2,

they found that the traditional way of cataloging was less functional in the Internet environment. They began creating a new standard for cataloging called the RDA (Resource Description and Access), marking a fundamental change in cataloging practices.

The MARC record has been at the center of cataloging for more than 30 years and may be approaching the end of its life. As cataloging migrates to web-based standards such as Dublin Core and MODS (Metadata Object Description Schema), cataloging elements will retain their semantic value, the meaning of their controlled vocabulary, but they may lose their syntactic value, which comes from the precise order in which these terms are arranged. The many thousands of MARC records created in the twentieth century will still form the core of data for cataloging records into the future, regardless their format. Knowledge of music cataloging practices will continue to help library users find the music they seek.

CLASSIFICATIONS

Today most academic libraries in the United States use the Library of Congress Classification (LCC). The “M Schedule” for music,^[66] was devised by Oscar Sonneck in 1902 to meet the needs of an existing collection, the Library of Congress. Since its inception, LCC has been amended to accommodate popular music, world music, and other new areas of music research. Smiraglia’s *Shelflisting Music*^[67] provides guidance in how to construct LCC call numbers.

Conceived as a way to organize all knowledge, the Dewey Decimal Classification (DDC) was drafted by Melvil Dewey in 1876. Adopted by public, research, and some academic libraries the DDC is the most used classification globally.^[68] Inherent problems in DDC were its inability to adapt to new musical forms and genres and its lack of a provision to separate music scores from music literature. Some libraries addressed this problem by adding a prefix “M” for music scores before the Dewey class number while others elected to reclassify their collections to LCC. The revision of “780 Music” of Dewey (DDC20) attempted to resolve these problems by creating a faceted system allowing scores to be segregated from music literature. It also added classification numbers for folk and popular music and modeled the classification of musical instruments on the wider encompassing Sachs–Hornbostel system which distinguishes instruments by how sound is produced.^[69]

Over the years, a number of music classification systems were formulated as examined by Krummel,^[70] Elliker,^[71] McKnight,^[72] and Bradley.^[73] For example, a classification specifically for music scores was devised by George Sherman Dickinson, Professor of Music, and the first music librarian at Vassar College, Poughkeepsie, NY (USA). In his classification system, *The Classification of Musical Compositions: A Decimal-Symbol System*,^[74]

published in 1938, Dickinson recognized that not one system could serve each library type equally. The result is a system that can be modified to conform to different types of music libraries and the needs of their users. The Dickinson classification system was used by a number of music libraries in the northeastern United States. However, because the Dickinson classification utilizes special music symbols, many libraries have adopted classification that are more compatible with integrated library systems.

For audio collections, libraries may choose not to classify recordings but to organize them in accession order. This arrangement offers the most economical use of space because room is not left to interfile new items. Some music libraries elect to use the record label and label number as a way to organize recordings. Both arrangements have the benefit of avoiding the decision of where to classify a disc when it includes works of different genres by different composers.

If recordings are classified libraries often adapt LCC or DDC. Some music libraries use the *Alpha-Numeric System for Classification of Sound Recordings* (ANSCR)^[75,76] intended to facilitate browsing in public libraries. ANSCR arranges recordings in a hierarchy of subject, composer or subcategory, title, and performer’s name.

PRESERVATION

Music libraries will continue to have LP and CD collections, as well as collections of recorded magnetic tape in various formats. The challenge in keeping these collections valid and useful is twofold: preservation and access. An LP is a great medium for preservation; even discs 60 years old or older will play well if not worn, warped, or scratched. However, challenges remain of maintaining working playback equipment and obtaining replacement parts. Magnetic tape formats are becoming obsolete and finding working playback machines is becoming difficult. For these reasons, many libraries are digitizing their analog collections for purposes of preservation and access.

Preservation needs to be considered even for digital formats. The oldest CDs are now nearly 30 years old. They can be subject to oxidation and damage from wear and tear. Digital media require migration to newer digital formats to keep them useful. Sound recording archivists held a conference at the Library of Congress in 2001, which took into consideration problems of access, preservation, and intellectual property for folk heritage sound recording collections.^[77] Most recently, Indiana University and Harvard University published audio preservation standards^[78] based on their tests of new technology.

For print collections, attention must be taken to process materials for long-term use. Since music is used in performance, it must be bound to lay flat on a music stand. Special binding provisions are needed for parts,

comb bindings, and nonstandard sized items. Carli's *Binding & Care of Printed Music*^[79] presents a detailed examination of the issues of paper conservation and binding and offers how-to information for in-house conservation steps.

ETHNIC AND WORLD MUSIC

Music libraries have traditionally collected materials in Western classical music, but ethnic and world music have become common in collections over the past three decades. In 1994, MLA published a technical report examining world music in libraries.^[80] The term "world music" is a popular current alternative for such terms as primitive, non-Western, ethnic, and folk music. Its broadest definition is simply all types of music from around the world. In this context the definition expands beyond the purely popular idiom to include all styles of music with ethnic or foreign elements.^[81]

With the growth of worldwide systems of communication and commerce, librarians will feel increasing demands for materials characterized as world music. Reference questions pertaining to world music have become more numerous in recent years, as college and public school curricula have emphasized cultural diversity and interest in globalization. Music education majors now look for examples of ethnic music to teach in the classroom. Public librarians face ever greater numbers of patrons seeking music of their ethnic heritage.

The techniques used to handle Western classical music do not always easily apply to world music. Certain basic assumptions are made about Western classical music: that it exists in a written form and can be identified in an historical context from written sources; that the composer serves as the primary point of access; that uniform titles can be created according to what is found in written sources; and that subject access and classification rest on standard forms. World music is less likely to exist in a written form, since it may be passed on by aural tradition. The composer may be unknown, thus the performer, informant, or even the collector may have to serve as primary points of access. Music in aural traditions may vary with each performer and even with each performance. The title of a work may exist in variant forms and may not be found in any written source. Finally, world music frequently exists in forms and genres that cannot be identified in written sources, thus subject access and classification may require special provisions.

Many music reference tools also address world music; however, there are also specialized sources. One of the best is the 10-volume *Garland Encyclopedia of World Music*^[82] which is also available in electronic format. Each volume covers an area of the world. This work is not an encyclopedia in the traditional sense, where one could look up a specific term. Rather, it should be thought

of as a collection of well laid-out and illustrated scholarly articles written by experts. To find specific information, readers need to use the detailed indexes. Other specialized reference works are cited in annotated bibliographies by Schuursma^[83] and Post.^[84]

Subject access to world music presents special problems. LCSH are designed for use primarily with Western classical music. A basic tenet of these headings is that they tend to use genre or form of a composition as the initial entry point. This becomes a problem with world music, because it tends to scatter headings of music from a specific geographic region throughout the catalog. Examples of LCSH for Japanese music include: "Ballads, Japanese," "Buddhist hymns, Japanese," "Folk Songs, Japanese," "Hymns, Japanese," and "Songs, Japanese."

Another tenet of LCSH is that they use only the most specific heading that fits and typically do not add more general headings. For example, Japanese koto music would receive the subject heading "Koto music" and not "Music-Japan." If this music is in a specific form, such as a sonata, it would be cataloged under "Sonatas (Koto)." Patrons need to know details about the music in order to find the specific subject heading.

Libraries with large collections of world music have tended to use the Murdock's *Outline of World Cultures*^[85] to augment subject access to their collections. Additional information about subject access to world music materials may be found in Kaufman^[86] and in Pierce.^[87]

FUTURE CHALLENGES

Music, as a humanities discipline, has been slow to enter the digital environment. While journals were the earliest format to be digitized in other fields, music journals are relatively recent inclusions in *JSTOR* and *Project Muse*; however, other music formats are much further behind. Projects for digitizing musical scores are uneven in coverage and not fully developed. The physical practicalities of using digital scores for performance have yet to be successfully addressed. Currently, some databases of copyrighted music permit access to scores by allowing users to pay per item download. Others allow users to view scores for study purposes but not to perform from the digitized versions. Digital audio content from commercial databases is broadening, but is still representative of only particular recording labels or specialized subject areas. Alarming, lacking are provisions for perpetual access to the content of these digital audio and music resources. In addition to physical hurdles to overcome, in general, non-book materials are plagued with much more complex limitations imposed by copyright law than are books.

Because music materials are not in step with other disciplines, music libraries have been slower to feel the problems and challenges which face general libraries in the first decade of the new millennium, and music

librarians are only beginning to realize these changes in their daily work. In the area of collection development questions of access vs. ownership are further complicated because not as many music-related items are yet available electronically. Music publishers tend to be small businesses and are often reluctant to fund the development of new electronic resources.

Aside from digitization, music-related materials themselves are changing. For example, the field of music study has expanded in new directions. It is increasingly interdisciplinary, focusing on cultural, ethnic, racial, and gender issues, and requiring new reference tools and resources.

The future of sound recording looks very much like the past. The issue of retention of older formats and their playback equipment while acquiring new formats continues to be a challenge. The history of sound recording has been characterized by competing formats, and we still have competing formats today. Digital files can be in a variety of formats such as WMV, RealAudio, MP3 and AAC. There is absolutely no guarantee that today's audio file will play on a computer even 5 years from now, let alone into the foreseeable future. All digital file sound recordings, just like other computer media, will have to be migrated to newer formats as they are developed and become the standard for that time.

In the digital age, academic music institutions are expected to provide course reserve listening assignments in digitized form. This new service requires acquisition and training in the use of software and hardware, beyond the simple scanners needed by their counterparts in other disciplines.

The Indiana University Digital Library Program proposes to create Variations3, a digital music library system, modeled after Indiana's highly successfully electronic Variations music library, which can be deployed at other academic libraries. In support of instruction and learning, the system will enable institutions to digitize and provide online access to recordings and scanned scores for use with annotation and analysis tools.^[88]

Historically, music libraries have been somewhat autonomous from general collections because of their many nontraditional needs. Integrated library systems provide a benefit for increased collaboration with colleagues in other disciplines but also a downside. With integrated library systems the special needs of music materials often take a backseat to the general needs of book materials. Music libraries are finding themselves pressured to standardize procedures and to abandon specialized classifications.

However, new technology can offer new opportunities. It is hoped that new digital resources will offer a wider range of access points tailored to musicians' needs such as song text, date of composition, exact instrumentation, edition, and type of score. Especially useful would be sources that display for recordings liner notes and for scores the first page of music, if not the entire composition, to allow

users to view editorial practices, typography, and page layout.^[89]

While the idea of librarians as teachers is gaining acceptance in all disciplines, students especially benefit from help in evaluating music resources and effectively finding music materials in the largely book-oriented library online catalogs. The expanding interdisciplinary scope of music research brings new patrons who need to familiarize themselves with the different procedures, equipment, and classifications found in music libraries. Blotner observed greater need for instruction to address the growing number of databases.^[90] Users seek help in selecting the appropriate database to consult, in formulating search strategies, and in evaluating search results. Recognizing this need, in 2004 MLA published *Music Library Instruction*.^[91] Physical barriers that are inevitable with separate music library facilities or collections are reduced through electronic access to portions of the collection or to a music librarian by email, chat, blogs, and social networking tools.

Space issues are increasingly a problem for many older libraries and music libraries are no exception. As patrons look to accessing audio music and course reserves from their computers, academic libraries are using space formerly devoted to on-site listening areas to meet other needs. Computer work areas, group study spaces, and classrooms are taking their place.

Digitization of reference tools and primary resources offer an opportunity to improve reference service and foster communication with a broader range of users. The future of music librarianship requires that music librarians, who best know the field of music and its users, advocate for and participate in the design of music reference tools, library systems, and digital resources that advance music scholarship and satisfy the needs of those who study, perform, and enjoy music.

Name Authority Control

Janifer Gatenby

Online Computer Library Center (OCLC), Leiden, The Netherlands

Karen Smith-Yoshimura

Online Computer Library Center (OCLC), San Mateo, California, U.S.A.

Abstract

The purpose of name authority control is to facilitate searching and browsing by 1) ensuring retrieval of all the works of a person, personal identity such as a pseudonym, family name, or organization where they may be published under different name versions over time and in different places; 2) enabling other works by the same identity to be retrieved from any one work; 3) by eliminating works of other identities with the same name; and 4) by concise name indexes that ensure efficient browsing. Authority records may include name variants, and these are distinguished from related names of other identities of the same person. Records also contain differentiating information and, most importantly, identifiers that are the key elements facilitating linking. Differentiating information differs for personal and organization names. The creation of authority records is a labor-intensive process, and the trend is toward creating locally and sharing internationally. Consolidated sources are important for facilitating reuse and as key resources in linked data. Input data are accepted from a variety of sources, including biographical sources, encyclopedias, institution records, and crowdsourced systems. Different models and encoding systems are detailed.

INTRODUCTION

There are multiple purposes of name authority control. Firstly, name authority control facilitates searching and browsing by ensuring retrieval of all the works of, or about, a person, personal identity such as a pseudonym, family name, or organization where they may be published under different name versions over time and in different places, and ensuring that they are retrieved with the same form of name that the specific community will understand (e.g., “Confucius” in Anglo-American communities, and “孔子” in CJK [Chinese, Japanese, and Korean] communities). Name versions differ in different languages; in particular, transliteration practices differ by language. There are also differences in name forms among regions sharing the same language such as Belgian Flemish and Dutch name forms. Geographic names are prime examples: Firenze (Italian), Florenz (German), and Florence (French and English). Name authority records also enable other works by the same identity to be retrieved from any one work, at the same time eliminating works of other identities with the same name. Name indexes can be created from authority records instead of bibliographic records so that the indexes are more concise, ensuring faster and more efficient browsing.

In librarianship, name authority control is traditionally the process of collecting together different versions of a name and recording them together in a name authority record along with differentiating information. Names in bibliographic records’ access points are linked to name authority records either via a name form or by an identifier.

In traditional library practice, the authority record indicates a preferred name form that is used in bibliographic records. The most common form of name used in the official language of the community is generally selected as the “preferred form,” and the preferred form can vary from one community and language to another. Where there are different persons or organizations sharing the same name, the usual practice is to extend the preferred form of name in an authority record with additional differentiating information such as dates or profession in the case of persons, and location in the case of organizations. However, identifiers are now replacing the concept of preferred name.

NAME CONTROL OR IDENTITY CONTROL?

As stated earlier, name authority control allows the differentiation of different persons and organizations with the same name. The International Standard Name Identifier (ISNI)^[1] makes a clear distinction between a name, an identity, and a person or an organization. A person may have one or more names, such as a maiden name, married name, change of sex name, and name in a different script, but only one identity. A person may also have one or more identities that he or she uses to present creative works publically. Where a person has multiple name forms, within a MARC (Machine Readable Cataloging) authority record one is marked as preferred and others as name variants. The Virtual International Authority File (VIAF)^[2] and ISNI, being crafted from multiple sources, have moved away from the traditional library concept of a

preferred form of name, allowing preferred names to differ according to source. Preferred name is challenged by some professional communities that do not designate “one preferred form” but identify which forms are used in particular contexts, both geographic and temporal.^[3] For scholars, VIAF and ISNI have not gone far enough, but the notion of a preferred form of name is endemic even outside the library community, for example, in the knowledge organization systems (KOS) such as thesauri, classification schemes, subject heading systems, and taxonomies, and that is reflected in the W3C SKOS standard.^[4]

NAMES AND NAME VARIANTS

Meryl Streep has only one public identity that she uses for her creative works. VIAF includes Streep, Meryl (Mary Louise), as the name form on her birth certificate is Streep, Mary Louise. Her married name Gummer, Mary Louise, is mentioned in Wikipedia and could also be considered as a name variant (Fig. 1). Changes in the preferred forenames and change of name due to marriage are not considered as constituting a change of identity as there is not necessarily a wish by the person to separate his or her creative output corresponding with a name change. Researchers, for example, will mention the ensemble of their publications in their curriculum vitae where they have been published over a lifetime involving name changes.

Alternative name forms that do not usually indicate a change in identity can take variant forms including names in different scripts or transliterated with different schemes, changes due to change of sex, marriage, or legal declaration.

PSEUDONYMS AND MULTIPLE IDENTITIES

Kingsley Amis in Fig. 2 is an example of an author writing under three different identities: writing as himself and writing under two different pseudonyms. His works attributed to each of the three different identities are clearly separated. In this case, the association of pseudonyms with the real person is public but that is not always the case. For example, J.K. Rowling chose to create a pseudonym Robert Galbraith^[5] so that she could write in a different genre and have her works in the new genre judged without any influence of the successful Harry Potter series. When the relationship between a pseudonym and a real person is or becomes public, the works tend to become associated with the real person as well as the pseudonym; for example, they may be republished or released in collected works. One example is John Wyndham, the main pen name of John Wyndham Parkes Lucas Beynon Harris (July 10, 1903, to March 11, 1969). Under an earlier pen name, John Beynon, he wrote *Secret People*, but this is now published under John Wyndham. As a general rule, separate authority records should be made for each identity used as a public identity. This allows the history of works to be accurately traced, enabling catalogs to respond to questions such as “under which identity was the work conceived and first published?” The authority records related to each of the public identities should be linked where the relationship is public. Encyclopedias such as Wikipedia tend to have only one entry for a person, grouping all public identities. This entails the need for one-to-many relationships in linking especially

from library authority records to encyclopedias. For example, VIAF links its clusters to Wikipedia and ISNI includes MusicBrainz links in its records (including links to library authority records).

Figs. 3–5 from VIAF indicate that VIAF and ISNI have three separate records for the three separate public identities of Kingsley Amis. All but one VIAF source considers Robert Markham to be a separate identity, whereas two sources (National Libraries of Poland and Catalonia) have declared the name as a variant name.

When is there a change of identity? Authority records include name variants and related identities. Practices differ among libraries. The same name can be declared to be

a name variant by one library and the name of a related identity by another. The VIAF includes many examples of these among its clusters, as in the case of Robert Markham. As the concept of public identity is core to ISNI, and giving separate ISNIs to each separate identity is critical,

Fig. 3 Image of VIAF cluster for Kingsley Amis.

the ISNI Quality Team has produced a policy document^[6] defining when a name form should be regarded merely as a name variant or as belonging to another identity (both identities being linked in the ISNI database by a “Other identity same Person” link) and is working closely with VIAF to encourage adoption of consistent treatment.

UNDIFFERENTIATED NAMES

Many library systems include a feature that will generate name authority records from the name forms in the name fields in bibliographic records. Links are then made between the generated authority records and the name fields from which they were derived. One such system is Centraal Bibliotheek Systeem (CBS), used by the Deutsche Nationalbibliothek (DNB).^[7,8] The DNB makes a distinction between the records that are generated by program and those that are made by catalogers using biographical information from multiple sources including that published within a work, encyclopedias, and contacts with creators directly or through their publishers. However, it should be noted that not all undifferentiated names are machine-generated. For example, in Library of Congress/Name Authority Cooperative Program (LC/NACO),^[9,10] undifferentiated authority name records have been created by catalogers for the purpose of making catalog access points where there was insufficient information available at the time to create separate authority records. Undifferentiated authority records control a name string and may bring together works by different identities sharing the same name string. They serve a purpose to facilitate search and browse within the file in which they were generated. However, their utility beyond the one file is limited. Undifferentiated data cannot be used confidently in a broad networking environment and become a serious problem when exposed in Linked (Open) Data. For this reason, the Program for Cooperative Cataloging has a new policy as of November 13, 2013, stating that no new undifferentiated authority name records will be created.^[11]

ORGANIZATION NAMES AND HIERARCHIES

Organizations, including institutions, corporate bodies, and less formal groups of individuals, pose their own problems for name authority control. Like individuals, names may change over time without a change of identity, for example, a university library may be given the name of an emeritus person. Organization names are often abbreviated and the sequence of words within a name string may be altered, for example, the University of Sydney and Sydney University. These are examples of name variants for organizations. More often, a change of name reflects a change in scope, purpose, or ownership, constituting a change of identity. For example, a name with the

same words in a different sequence can sometimes be the same organization and sometimes a different organization and many abbreviations and acronyms can be shared among identities.

Organizations raise other issues from their structural perspective. The same name may represent separate identities for the same organization—a legal, a commercial, a branding, and a contracting identity. Some of the organizations, depending on the nature of their activity, insist on the need for separating these identities. Organizations also have hierarchies. Depending on the needs for information processing, representing these hierarchies can be very important.^[12] Within authority records, hierarchies can be represented using related name fields plus relationship type.

DATA ELEMENTS: DIFFERENTIATING CRITERIA AND INFORMATIONAL METADATA

In order to separate different identities with the same name, library authority records include differentiating elements, in particular date of birth and/or death that may be included in the preferred name form. In the preferred name form, distinguishing data may also be included such as occupation, fuller forms of forename, and name qualifiers such as Jr. (Junior). More data can be included in supporting fields such as the new MARC fields introduced for compatibility with the new rules Resource Description and Access (RDA)^[13] that allow for more granularity in data encoding and, therefore, provide new possibilities for exploiting the information. These are special coded dates, associated place, address, field of activity, affiliation, occupation, gender, family information, and associated language.

Other data included in authority records that also play an important differentiating role include titles of works, identifiers of works, associated languages, and occupation. VIAF considers coauthors and performers as well when merging or differentiating, and ISNI has extended the differentiating criteria to include instrument and voice for musicians and performers.^[14]

The important elements for differentiating organizations with the same or similar name strings are geographic location, organization type (e.g., university or hospital), and name use (e.g., legal or brand).^[15] Dates are important for organizations as well. However, they are less frequently included in the authority records than those for persons as they are not widely known. Therefore, the use of dates as a criterion of disambiguation for organizations in automated processing is less reliable. Similarly, works published by organizations tend to have generic titles such as “Annual report” and so are less useful for disambiguation of organizations. Relationships between individuals and organizations are important complementary elements. A person record can include institutional affiliations and links to other persons. Organization records can include

links to related persons and to other organizations. Recording the precise type of relationship is now replacing the more generic “see also” that is implied from the existence of the related field within an authority record.

The International Federation of Library Associations (IFLA)’s mandatory elements for internationally shared resource authority records (MLAR) report recommends mandatory elements required for records to be suitable for international sharing.^[16]

In other domains, the emphasis on differentiating criteria can vary. Encyclopedias such as Wikipedia^[17] and MusicBrainz^[18] tend to use similar criteria to libraries, whereas Rights Management Societies may use passports and other official documents, together with dates, all of which is regarded as confidential data. ORCID^[19] relies on e-mail address as the main differentiating element, and this is usually marked as confidential.

Archival authority records, though built on the library authority control tradition, are in general much richer than library authority records. The identity part of information, that is, the management of names, is much in line with the library practices. The difference is in the descriptive information about the entity. While libraries tend to create detailed records for bibliographic resources and smaller authority records with just enough information to differentiate identities, archival authority records include extensive, supportive, descriptive information such as biographical and genealogical data, called “contextual information.” The detail in archival authority records can be richer than that in the records of associated resources.

Archival authority records, however, need to support a much wider set of requirements than is the case with library authority records. These additional requirements are associated with the importance of documenting information about records creators and the context of records creation in archival description systems. As such, archival authority records go much further and usually will contain much more information than library authority records.^[20]

RELATING BIBLIOGRAPHIC AND AUTHORITY RECORDS

Many libraries exemplified by the contributors to the LC/NACO file link from bibliographic records to authority records principally by name string. The name string of the preferred name form is included in the bibliographic records with optionally a reference to the authority record identifier. The fact that preferred name forms may contain dates and qualifiers that are nonname elements reflects this usage. While it allows the use of authority records without imposing actual links, it has limitations:

- The preferred name form in the authority record needs to be stable, so dates are not consistently added to

headings where known and they are not updated when a person dies, though they can be recorded in other fields in the authority record.

- Differentiating metadata is in both the preferred heading and in supporting fields within the authority record.
- It necessitates the choice of a single preferred name form, whereas many name variants merit equal weight, for example, in a bilingual or multilingual country such as Canada or Switzerland. Name forms in multiple scripts provide another example where multiple preferred forms should be possible.
- It makes global changes of bibliographic records a lengthy practice where each corresponding bibliographic record needs to be updated when the preferred name in an authority record changes, for example, in the case of a typographical correction or a change of name.
- In the case that it is necessary to split an authority record into two or more separate identities, the global change procedure is even more complicated and inadvertent omissions are common.

Many library systems store only an identifier in the bibliographic record, making global change a far less onerous task but as not all do, these problems remain, particularly when records are split and one identifier is retained.

To begin to overcome these problems, it is necessary to systematically use identifiers when linking from bibliographic to authority records. This is a new recommendation of the Program for Cooperative Cataloging.^[21]

IDENTIFIERS

Where multiple preferred forms are allowed within an authority record, identifiers become the essential element and are used for reliable linking. The number of data elements necessary to establish identity and distinguish from other identities with the same name varies depending on the commonness of the name. For example, two persons could have the same name and be born in the same place on the same date. In this case, the name of their parents or other data elements such as profession would differentiate them. Because the number of elements is not finite, identifiers serve to act as shorthand for the ensemble of metadata elements within an authority record. Identifiers are concise, easily sharable elements, and are the key elements in linked data. In 2008, an IFLA Working Group on Functional Requirements and Numbering of Authority Records^[22] concluded that development of a system of international scope to issue and maintain authority identifiers was unlikely to happen. Nevertheless, they recommended the use of the VIAF cluster number as an alternative with a close watch on the development of the ISO working group on the ISNI. Three years later in

November 2011, the ISNI-IA announced the ISNI database with 1 million assigned identifiers. In 2 years of operation, the number of assigned identifiers has grown to 7.5 million with 30 contributors.^[23]

The key identifiers for international use are ISNI, VIAF, and ORCID. ORCID started in 2012 with the aim of providing identifiers for researchers to use in submission of articles for publication and in grant applications. Thus, an ORCID can be assigned and an authority record can be born before the researcher has actually published. Another identifier that is used internationally is the Interested Party Identifier (IPI) of the International Society of Authors and Composers (CISAC).^[24] This identifier is used in the music industry in particular, but access to it is restricted because it links to confidential information. Thus, CISAC became one of the early drivers of ISNI to act as an independent neutral identifier for cross-database and cross-domain linking.

RECORD CREATION AND REUSE

Creating high-quality authority records takes time and research. The training for LC/NACO certification is 5 days.^[25] The British Library, for example, often contacts authors through their publishers to determine whether they have previous publications. Apart from a work in hand that may contain biographical information, there are many sources on the web that can be consulted including encyclopedias such as Wikipedia and MusicBrainz, personal web pages, institutional web pages, biographical dictionaries, and trade information such as Scholar Universe,^[26] Scopus,^[27] Web of Knowledge,^[28] and Amazon.^[29]

Considering the high cost of creating authority records, libraries seek to reuse existing authority records wherever possible. Records made by national libraries are made available to other libraries for reuse.

In the mid-1970s, the Program for Cooperative Cataloging established the LC/NACO program and database that currently includes over 7 million records. As well as the Library of Congress, participants include the British Library, National Library of Medicine, National Agricultural Library, and national libraries of Mexico, New Zealand, Scotland, South Africa, and Wales, and over 200 other participant libraries.^[30] The records are freely available via web search and as linked data. The LC/NACO file contributes to VIAF that started in 2003. In January 2014, VIAF included 33 sources, of which LC/NACO is just one. National libraries and library networks worldwide have contributed to VIAF as well as the Getty Museum and Perseus Digital Library hosted by Tufts University. Wikipedia data are harvested and appear as a source within VIAF, and ISNI started contribution to VIAF in 2013. VIAF clusters data from its sources and makes it available for consultation via a web interface and by an SRU API (Application Program Interface). The data

are also available for harvesting by bulk downloads and for diffusion as linked data. VIAF contains 34 million authority records, of which more than 26.4 million are personal name and 5.1 million are corporate name records. Name/title (1.8 million) and geographic name (400,000) authority records make up the total. It has become a significant international resource for libraries and linked data. This is evidenced by its traffic with close to a million personal visits a year.^[31]

VIAF is a major source within the ISNI database. ISNI is an international database maintained by a not-for-profit consortium, the ISNI-IA. The database scope is different from VIAF; though it includes VIAF, it does not include its name/title records, meeting, or geographic name records and excludes undifferentiated and sparse records. On the other hand, ISNI's scope is larger than VIAF with 28 other contributors from multiple domains: rights management, trade, and education and professional societies. In particular, it includes more researchers, musicians, and publishers. Like VIAF, ISNI's data are clustered, but the records are flagged for confidence and there are strict rules for assignment. ISNI also defines extensive vocabularies, for example, creation roles, relationship types, organization types, name use, and matching types. There is a freely available web interface and SRU enquiry API and RDF (Resource Description Framework) serialization.^[32,33]

Name disambiguation is a common requirement for databases in multiple domains. Rights management societies collect money for reuse of resources and need to track down rights holders. Online stores such as Amazon and iTunes need disambiguated identities in order to provide, for example, "more by this author or performer" searches and biographical information. Search engines are also beginning to provide such information. Examples are Amazon's Author Central program^[34] and Google's knowledge graphs.^[35]

Just as libraries use external sources for creating authority records, their records are being reused in other domains. The major Internet search engines harvest data from VIAF and ISNI such that, for example, the VIAF search API accounts for 98% of external access and averages about 5 million searches a week.^[31] The lack of authority control in institution repositories has been recognized as a major problem for retrievability.^[36] The University of North Texas Libraries^[37] has estimated that less than 35% of researchers can be found in VIAF and LC/NACO sources. Consequently, it has built a name authority system that allows access to VIAF, LC/NACO, Wikipedia, and ORCID and builds links at the same time.

The level of reuse and sharing is necessary to enable libraries, archives, and all organizations involved in the creative domains to concentrate on local identities, especially as the scope of authority control must be broadened to include many more types of publication, both physical and digital. Name authority control of the authors of journal articles was long avoided by libraries but is now being embraced in cooperating systems such as ISNI and

ORCID and in the OCLC Research activity on registering researchers in library authority files.^[38]

CROWDSOURCING

Crowdsourcing is increasingly important for enriching and correcting data. A large number of databases are based on crowdsourcing such as Wikipedia and MusicBrainz, social networking sites, and professional networking sites such as Mendeley,^[39] RePec,^[40] AuthorClaim,^[41] ResearchGate,^[42] and PublicationsList.^[43] ORCID too is based on researchers self-registering.

The major drawbacks of sourcing data from the public at large are risks of incompleteness and inconsistency in detail and quality. Moreover, in the current information environment, quality is more needed than ever. The question is how to benefit from crowdsourcing as a powerful means of enhancing quality and enriching data in authoritative systems and at the same time making sure of the quality of the input. Such a model requires careful monitoring and a solid policy for resolving conflicts. ISNI has setup a monitored crowdsourcing system. The general public is encouraged to enrich and correct data, but the data that are collected trigger an e-mail alert to the Quality Team at the British Library and the Bibliothèque nationale de France. In this way, ISNI strives to achieve a balance between curated data from the library world and other domains and individual knowledge. ORCID too is striving to find a balance between data input by researchers and that input on their behalf by their institutions.

MATCHING AND CLUSTERING

VIAF and ISNI collect data from multiple sources. Both use similar matching algorithms; VIAF then creates clusters and ISNI creates composite records. Where names, dates, and title of a work match from different sources, a match is made. In the absence of a direct match, other metadata elements are considered such as subjects, classification, active time period, nationality, coauthors, institutional affiliations, publishers, instruments, and uncommon title words. In addition, ISNI assigns two confidence scores; one in the data itself and another in the matching. Some records are flagged as possible matches needing manual review or retry against new data or with revised matching algorithms. ISNI also seeks to find sources that are rich in elements that can help cluster sources with different differentiating elements. For example, MusicBrainz encyclopedia was harvested so that it could help match data from the performers' rights management data that contains identity dates and instruments with other sources containing names and works only.

LINKED DATA

In the words of Corine Deliot of the British Library "Linking is not a new concept in librarianship. Within databases, bibliographic records contain links to authority records. Even WorldCat, to which thousands of libraries worldwide contribute, links to only one name authority file, to LC/NACO. The newly coined linked data extend links beyond databases to multiple Internet sources. The Internet was a method of linking computers (useful, but difficult, and not interesting to most people); the Web is a way of linking content (pages) held on computers (interesting and useful to people); linked data are a way of linking information (interesting to people and very useful to machines). This opens up new possibilities for machine to machine processing and new services that depend fundamentally on accurate identification of entities." Linked data add context to links and provide to bibliographic databases the capability of links to a myriad of authority files and resources.

Cross-domain linking is a trend. Wikidata, the pool available to all language versions of Wikipedia, has been populated with VIAF and ISNI identifiers via the "VIAFBot," and so far the German and English versions of Wikipedia include these identifiers.^[44–46] In the Netherlands, the universities' Current Research Information System called National Academic Research and Collaborations Information System uses the national union catalog's authority file to register researchers receiving government funding.^[47]

Links too can be complicated, not necessarily a simple one-to-one relationship as is seen in the case of Wikipedia that generally has just one page per person, grouping all known pseudonyms. One-to-many and many-to-one links are necessary.

Error correction is a major challenge with linked data. The more links there are, the more difficult it is to stamp out an error in the same way that it can be difficult for a person to suppress a former address. ISNI (which has 18 million links) has a notification system that pushes error corrections to all known sources. Acceptance of such notifications is a condition of ISNI membership and data contribution.

ENCODING AND MODELS

Data models, data rules, and encoding are closely related. Rules determine the semantics of data elements and how to construct them, for example, how to abbreviate and how to sequence elements. Examples of rules for library cataloging include *Anglo-American Cataloging Rules*, 2nd ed. (AACR2),^[48] *Personennamendatei* (PND),^[49] and the French rules AFNOR NF-Z44-061.^[50] RDA^[13] has been introduced first to replace AACR2 but is likely to become an international cataloging code replacing all the national and regional rules. In the archival world, there

is ISAAR (CPF).^[51] The early library rules have a common model of a bibliographic record for a publication linked to one or more authority records (names, subjects, places, etc.) where names of authors, editors, illustrators, translators, etc., are linked to authority records. RDA are new rules brought into being for two main purposes; to be international rules that could replace the myriad of national cataloging codes and to reflect a new model, Functional Requirements for Bibliographic Records (FRBR)^[52] and its associated Functional Requirements for Authority Data (FRAD).^[53] In the new model, the production of bibliographic data is not viewed as simply creating bibliographic records but as a process of creating descriptive information about the four FRBR Group 1 entities; the work (original creation), expression (content level), manifestation (publication level), and item (physical level), as well as information for the Group 2 entities (agents) defined by the FRAD model. RDA also articulates the roles of authority records that can be linked to any of the three theoretical FRBR levels. For example, authority records for authors and composers are linked at the work level, whereas translators, illustrators, and performers are generally linked at the expression level and publishers may be linked at the manifestation level.

There are many standards in practice for encoding authority records. Schemas determine the name of record elements and how they are structured. They include MARC in its many variations, in particular, MARC21^[54] and UNIMARC^[55] and MADS,^[56] with various encoding options, including ISO 2709, XML, RDF, Turtle, and JSON. The experimental Bibliographic Framework Transitions Initiative (BIBFRAME)^[57] is being developed as a replacement for MARC21 and a general model for expressing and relating bibliographic data, including name authorities. In addition, the emerging BIBFRAME authority schema^[58] may serve as an enriched alternative to the schema.org^[59] schema that is used by major search engines to harvest metadata from web pages. In the archival world, there is EAC-CPF,^[60] natively expressed in XML with alternative serializations in RDF.

TRENDS

Libraries have traditionally shared their data, and that sharing is increasingly international and cross-domain with the emergence of freely available, consolidated sources such as VIAF and ISNI as databases, enquiry targets, and linked data. The data are being harvested and used in library systems as well as institutional systems and Wikidata and Wikipedia. Maintenance of authority data is federated with an emphasis on local creation and international sharing. With increased sharing, there is a greater need for standard and consistent labeling of such things as

pseudonyms and for usage of common vocabularies such as relationship terms and organization types. It is important to maintain data locally and also within consolidations to ensure correct clustering, data consistency, and quality linked data. Multiple web sources and linked data are facilitating information gathering as library and archive data are coming together with data from multiple domains and crowdsourced resources. Authority data are being extended to link from all types of creative works, physical and digital.

ACKNOWLEDGMENT

The author wishes to acknowledge the very valuable input from Anila Angjeli, Pauline Chougnnet, Alan Danskin, Corine Deliot, Michael Docherty, Andrew MacEwan, Richard Moore, Karen Smith-Yoshimura, and Alison Woods.

National Archives

Helen Forde

Department of Information Studies, University College London, London, U.K.

Abstract

The scope of this entry covers the development of national archives from antiquity to the present day, charting the changes in the understanding of what constitutes a national archive and the differences between countries throughout the world. It looks at the different positions of national archives within governments, at their varying responsibilities, the scope of their holdings, and the activities which they undertake.

INTRODUCTION

National archives are the repositories of the selected records of government, in whatever medium, normally preserved in a government building and made accessible to the public. As in other archives they gain their authenticity from retention in official custody which in this case maintains their value as evidence of decisions and subsequent implementation by government. The reasons for maintaining a national archive are also much the same as for any other archive but often on a larger scale; the official record plays a role in society by ensuring that the rights of the individual and of government are documented and retained over time. Thus a national archive may contain diverse material ranging from treaties or boundary agreements on a national scale to the personal details of births, marriages, and deaths or the financial rights of individuals. The word *archive* covers both the historic records and the organization which looks after them but the context makes it clear which definition is referred to.

The concept of a national archive appears relatively simple at first sight, but on further investigation proves to be a highly diverse subject with many variations. This discussion is necessarily limited, due to the global scope of the subject and the availability of information, but the recent comparative work undertaken by the European Union (EU) demonstrates the value of deeper investigation. It is also clear that the concept changes and develops over time depending on the regime which it documents; these changes will continue, not least as greater global importance is placed on the right of all citizens to official information.

The footnotes indicate the main sources used and it must be emphasized that where examples are given the information is provided by the country cited and it has not been possible to verify it independently. It should also be noted that they are intended to be exemplars only and citing one does not mean that other countries do not follow the same practices. The regions of the world cited are those adopted by UNESCO.^[1]

HISTORICAL CONTEXT

The concept of ensuring the survival of key government documents dates back to antiquity although the recording format has changed over the centuries. The need for administrations to make their promulgations and laws public initially led to inscriptions being made on stone and clay tablets, foreshadowing the more sophisticated use of papyrus, parchment, paper, and ultimately electronic documents in the hands of those in power.

The survival of records in antiquity and their secure buildings is patchy—in some countries, such as Egypt, actual records survive but not the buildings; “Rarely indeed has there been a bureaucracy as record conscious as that of ancient Egypt. It not only used records as tools of management but also contributed toward making record—consciousness integral and important in the life of people”^[2] Elsewhere in the ancient world buildings, such as the Metroon in Athens or the Tabularium in Rome, which used to house the records of administrations, are known to have existed but their contents have not survived. The concept, however, was well developed and understood; for example, the tradition of keeping the royal archives with registers of the documents in Babylon was maintained by Alexander, the Great when he conquered the Persians in 333 B.C. The Greeks also influenced later Ptolemaic and Roman Egypt, bringing enhanced administrative skills which included quite sophisticated record keeping. In the Roman Empire, the Tabularium became the seat of the imperial archives after Caesar before the system was reformed by Diocletian (284 A.D.) and the previously centralized government became a migratory body, taking its documents with it. Many of such archives disappeared between the fifth and seventh centuries during the barbarian invasions in central and western Europe but the tradition of national—or at least regime—record keeping was to some extent maintained by the Arabs. Evidence for this is found in the Fatimid administration of Sicily from the tenth

century where advanced techniques of making, arranging, and preserving the records of the administration were introduced.

Northern Europe lagged behind these traditions, though by the time of Charlemagne (769–814 A.D.) codification of the law and some concept of the importance of keeping central administrative records must have been quite widespread. Evidence such as Domesday Book (1086), compiled for William the Conqueror in England, suggests that at least some of the information gathered for the survey was already available in written form by that time. The Normans instituted considerable administrative changes throughout their territories in Europe, including registers of grants and taxes as well as writs of instruction, most of which, in England were kept by the king in the Curia Regis and subsequently in the Chancery or government secretariat.

Elsewhere in Europe similar developments occurred, though frequently the archives related to powerful independent areas such as the city states in Italy, or the duchies in France. The archives of the kingdom of Aragon (modern Spain) date from 1346 and the first formal amalgamation of archives to form a type of national archive there occurred in 1542 with the foundation of the Archivo de Simancas. Two centuries later, the Hungarian historic archive was founded (1756) and most European administrations already held archival material essential for managing each country or region and its citizens by the end of the eighteenth century. However, the French Revolution is widely regarded as the moment at which the birth of national archives took place. The Archives Nationales, as an organization, was created in 1790 and legally established by law in 1794, centralizing the archives of France, making them available to the public and establishing an archival network throughout the country. The impetus came from the need to legitimize and preserve the archives of the new government, to rearrange those of the Ancient Regime and to take charge of confiscated documents regarded as part of the national heritage.

Similar changes occurred in the Netherlands, Italy, Germany, and Spain following the Napoleonic Wars of the early nineteenth century as the abolition of existing regimes necessitated control by new administrations. This confirmed the concept of a division between an historic national archive—relating to previous regimes—and current national records which in time would be selected for transfer to a place of permanent security.

Elsewhere in the world many of the governments and dynasties which relied on written communications had long established archives. The preeminent example is that of China where the magnificent chests in which the Ming emperors (1368–1644) kept their archives are still maintained in the Forbidden City in Beijing. Slightly later in Russia, Peter the Great initiated reforms when he issued an instruction to regulate transfers to the Russian Imperial

Archive in 1720, an interesting development demonstrating the importance he attached to the official record. Other countries or rulers also maintained their archives privately, for reasons of legitimacy, reference or self aggrandizement in a more or less complete state and transferred them to official national repositories when these were created. For some, this moment came with the expansion of government in the nineteenth century. In South America the Argentinean national archives was founded in 1821, the Mexican in 1823, the Bolivian in 1825, the Venezuelan in 1836, the Brazilian in 1838, and that of Peru in 1861. In Iceland the first national archive was housed in the attic of the Cathedral of Reykjavik in 1882; shortly afterwards, and on the other side of the world a national archive was created in India when the Imperial Record Department was established in Calcutta in 1891. As in some other countries a formal national archives was not established in the United States until the early part of the twentieth century since all government departments held their own records.^[3]

The catastrophic events of the two World Wars in the twentieth century precipitated further changes in the history of the national archives.^[4] Radical alterations to the constitutions and legal systems of Germany, Italy, and the Russian central and eastern European countries changed previous concepts and in 1992 Michel Duchein^[5] categorised three distinct groups as

- Centrally controlled systems in countries such as Bulgaria, Czechoslovakia, Poland, Romania, and the USSR where all archives, except for personal documents, were regarded as part of the state archive fonds following Lenin's decree of June 1, 1918 outlining their status.
- Dispersed control systems in countries such as Switzerland where each canton is separate archivally, with no national archive laws or standards.
- Intermediate systems in countries such as
 - Germany where the federal (Länder) archives are separate but a compliance system is enforced
 - Italy where provincial archives are part of the State Archive and municipal archives are controlled by regional Superintendents appointed by the Director General
 - Spain where the state archives have their own network of repositories but the regional authorities are given most of the archival power by the state
 - England where the national and local archives are not connected other than where public records, subject to the authority of the Lord Chancellor, are deposited locally
 - France where the national and local archives are governed by the same laws but the Archives Nationales is under the Director General of the French Archives and the local archives are under the supervision of the General Inspectors.

Since then the emergence of independent countries formerly part of the USSR, and changes in the Balkan areas of southern Europe have resulted in further developments of national archives. These have included Estonia which established a National Archive in 1998, Lithuania which did the same in 2004, and the Slovak Republic which created the National Archives Service in 2002.

Elsewhere in the world, the second half of the twentieth century saw a proliferation of national archive legislation and a burgeoning of national archive buildings and organizations. Information on these can be accessed from the relevant national archive Web site.

In the Pacific area these included

- The Australian National Archive which was created as a result of the Archives Act of 1983
- The Japanese National Archive which started as a government department in 1971 though it is now an independent agency following an amendment to the Archive Law in 2001
- The Malaysian National Archive created in 1963 although it was actually founded 6 years earlier as the Public Record Office and
- Archives New Zealand which was established in 2005 following new legislation although the archive had existed from much earlier.

In Africa many ex-colonial countries scrambled to establish archives as symbols of independence and legitimacy; these included

- Kenya which established a National Archives and Documentation Service in 1965.
- Mozambique which divided the library and archive to form a national archive in 1976.
- Ethiopia which opened its National Archives in 1979.
- South Africa where the State Archives Service became the National Archives in 1996.

Amongst the Arab countries

- The Lebanon passed legislation establishing the National Archives in 1977.
- Tunisia finally renamed the archive (which had served in various state capacities since 1874) as the National Archive in 1988.

In the Caribbean, national archives were established

- In the Bahamas in 1971.
- In Puerto Rico in 1972.
- in Jamaica in 1982.

The above are all examples, many other countries have established national archives and will continue to do so as administrations change and boundaries alter. However the

progression of national archives through the centuries demonstrates the importance attached to the secure maintenance of official papers and the legitimacy which the possession of such documents confers on a regime.

ISSUES

Reviewing the development of the national archives as described above it is abundantly clear that no two are exactly alike. The European Commission came to the conclusion that "It is impossible to say that there is a 'typical' 'National Archives service, exemplifying a general pattern, which applies to a greater or lesser extent throughout the European Union.'"^[6] If that is so for Europe, how much more true is it for the rest of the world, given the variety of histories, legal, and administrative differences?

Position of National Archives in Government

National archives are established by law in the country to which they relate. The provisions of each piece of legislation will dictate the activities undertaken by the directors and the staff of the archive, but all statutes embrace the three basic principles of selection, preservation, and access.

Different interpretations abound about the scope of these responsibilities, dependant on the financial and professional skill resources available. Selection of material is, in many ways, the most controversial since it is open to accusations of partisanship and bias, political, social, and economic. Even unwittingly archivists can shape the future historical perspective depending on which records are selected for permanent preservation and for national archives this may be a bigger issue than for a smaller, more local organization. This perception, of the official record whether it be national or local, has played a part in the proliferation of community archives, often established in localities or amongst the ex-employees of a business no longer operating, to add an additional, unofficial dimension to history.

The impact of freedom of information legislation has also accelerated the ways in which all public archival organizations have widened access to their holdings. Improved service delivery is a growing trend, with some of the national archives leading the way, not least since for the developed countries it has been possible to employ additional specialists who have skills in audience development, digitization, and education. The growth in interest in genealogy has been behind many of these developments and it has been possible to widen access to the relevant records as well as others following the development of digitization techniques. In consequence, a world wide audience is now a target for many access programs.

The different attitudes between administrations to the correct place for national archives within government are

clearly demonstrated by scrutinizing their location; the report on European archives in 2005 shows that the majority of the 25 national archives surveyed were the responsibility of the relevant Ministry of Culture (14); three others were situated within the Ministry of Education, two within the Ministry of the Interior, two within the Ministry of Justice, three within the Office of the Prime Minister, and one within that of Science policy.^[7] These statistics suggest that although it is widely acknowledged that archives are part of modern public administration, they, and in particular those which are sometimes referred to as historic archives, are more comfortably placed under the aegis of culture. In other parts of the world the same is broadly true, judging by those national archives which offer information of this sort on their Web sites. The Arab world has a tendency to give the oversight of the archives to the presidential or prime ministerial office as do a few Latin American countries but elsewhere the trend is toward culture and heritage. Many of these ministries have additional responsibilities ranging from the Status of Women (Canada) to Heritage and Sport in some African countries and in Australia, contributing to the impression that the organizations within their aegis are something of a ragbag. In just a few places, such as New Zealand, Japan, and the United States the national archive is a department or agency in its own right in government.

The variance in the position of national archives throughout the world is indicative of the problem of explaining their dual role in not only promoting access to the past but also in ensuring good current record keeping in government.

Responsibilities of National Archives

Strictly speaking, the scope of an archive of a government or regime would be limited to managing the records of the transactions of that body and its predecessors. In practice, the work undertaken in different countries is surprisingly variable. The titles have also changed over the years ranging from the very Victorian, and confusing, title of Public Record Office used in England and Malaysia (by now changed in both) to State Archives in Austria, Italy, Poland, and quite a number of other countries. "National" is the preferred term for most but transfer between the two has been quite common, the progression usually being from "state" to "national." South Africa switched from the title State Archives Service to National Archives and Record Services in 1996 with a mission to foster a national identity and the protection of rights. Swaziland is also very clear that these issues are central to the mission of the Swazi National Archives—which "is to empower Swazi citizens to fully participate in their country's social, political, and economic life through the equitable development, preservation, and protection of the Swazi cultural heritage."^[8]

These, and other similar statements elsewhere reflect the difference between the two terms, *state* denoting "a nation or territory considered as an organized political community under one government" and *nation* "a sovereign state of which most of the citizens or subjects are united also by factors which define a nation, such as language or common descent."^[9] Others however have adopted the term state with rather different meanings—in Denmark the State Archives is the collective name for the Danish National Business Archives, the Danish Data Archives, the Danish National Archives, and the four regional archives. In Georgia, the historic archive and the modern record archive are both referred to as state organizations although in practice they both contain much more than just the records of government.^[10] In Latvia, the State Archive consists of the Latvia State Historical Archive, the State Archive of Latvia, Latvia State Archive of Audiovisual Documents, State Archive of Personnel Files and 11 Regional State Archives, as well as the Archival Inspection, the Conservation Laboratory, and the Archival Training Centre with Library.^[11] The scope of the term therefore appears to vary according to the historical development of each archive and although some use the term national for specific reasons it seems likely that others are less concerned about the precise definition but more concerned to ensure that the various elements within the sphere of the archive are well looked after.

The governments of ex-colonial countries in many parts of the world have struggled with the concept of their former rulers that the records of the earlier administration are the property of the colonial power. In many cases, the provision of copies of the records concerned have been provided to ensure that the information about the ex-colony is available in the place of origin, but for some this is inadequate and disputes remain. Many of the arguments hang on the concept of *respect des fonds* and the integrity of the complete archive. Demands for restitution are often argued on the same basis as the return of museum objects to their place of origin. In the Philippine Islands, however, a conscious effort was made to re-create a national identity by handing over the Spanish archives of various agencies to the Americans at the Treaty of Paris in 1898, despite the fact that the records are in archaic Spanish and now rarely understood. "The National Archives, both as an institution of colonial creation and as a collection of records of colonial control, reinforces the *imagined* [my italics] idea of nationhood."^[12]

A few national archives are combined with libraries, either as a result of historic connections or as a rationalization of existing services. In Bolivia, the national library and archive have existed together since an economy measure in 1935; in Eritrea, the Research and Documentation Centre which is in the process of establishing the national archives encompasses the national library as well as other printed documentation and exists to collect all types of materials relating to the country. Much the same argument

was behind the formation of the national Library and Archives Canada where the two were merged as partners in 2004; the vision is that of being the “stewards of a collection that is the keystone of Canada’s national documentary heritage, a collection of national scope and importance.”^[13] In the United Kingdom, the National Archives is moving in somewhat the same direction but more as the centre for government information than as the provider of all official documentary material both manuscript and printed.

Scope of National Archive Holdings

The scope of national archive holdings might seem self-evident but in practice many have gaps in the records which they hold and many also hold material which might appear to be not strictly within a brief definition of their remit. Even the meaning of the phrase “national archive holdings” is not static since increasingly many countries include material amongst their holdings which is not necessarily the result of government activity but that of others in a government related role. This recognizes the value of nongovernmental organizations (NGOs), in particular, those that have been divorced from central government policy departments and operate in a more independent way. In effect, national archive policy must stem from and reflect current government’s means of working and ensure that as complete a picture as possible is maintained for future reference. Government is not limited to strict boundaries in an information rich society.

The narrow definition might also lead to the assumption that a national archive would have the responsibility for the selected material from *all* government departments. A quick look at the available evidence makes it clear that this is far from true. Disregarding secret or classified records the EU report on archives in the enlarged EU^[14] identified some clear trends; 12 of those surveyed took in neither the records of Parliament nor the Department of Defense, eight did not have Foreign Ministry records, four did not have the records of the President or Prime Minister’s Office, two had neither the records of the Department of Finance nor those of the Interior and one did not have material emanating from the Department of Justice. The omission of the records of Parliament are understandable since national archives are usually established for the executive arm of government and special arguments on security grounds may be adduced for the some of the Defense records, but many of the others seem to negate the principles of openness which democratic countries are at pains to proclaim. Only eight out of the 25 EU national archives held the records of all the major departments of government and three were denied custody of as many as five or six departments, seriously limiting their ability to ensure the survival of a full record of activity.

Information about the gaps in the holdings of other countries is hard to find as it is not included on Web sites and no global survey has been undertaken; however, it seems likely that all over the world some governments still restrict the scope of the holdings in their national archives while maintaining a cloak of democratic access.

Issues to do with access to sensitive material have dominated the history of national archives, in particular with changing regimes. Attitudes vary according to stance; those who are successful in overthrowing a government which they regard as illegal are often keen to demonstrate this by reference to archival material. For the same reason, the previous regime may have left much activity undocumented or destroyed material which could prove compromising. The Japanese government, as just one example, destroyed almost all the records of their wartime administration both at home and in occupied territories, but it has happened in many places at different times. Distrust of official custody has also made it difficult to resolve the eventual custody of reports and documentary material held as a result of national legal proceedings such as international criminal tribunals or truth and reconciliation commissions. In South America, Africa, and parts of Europe where the latter have been held, the issues have been very carefully considered to ensure that previous victims are comfortable with the designated repository for the archive. In the case of the reunification of Germany in 1991, the level of concern over free access to the Stasi files of the German Democratic Republic (which held immense amounts of personal detail) were so high that a separate archive was established to manage the records. Many German archivists felt that special arrangements were unnecessary and that this compromised the existing system, but a pragmatic solution had to be found. Other countries have had to resort to similar ways of dealing with highly sensitive material.

The impact of data protection and freedom of information legislation on national archives has been no less dramatic than for other archives—in many ways it has been greater. The resources allocated to ensuring that the right information is available to the right people at the right time have had to be huge; quite apart from the records management issues surrounding the custody of personal information in electronic formats the requirement to provide information freely has necessitated new procedures, additional departments, and dedicated staff. In many countries, the lead has been taken by the national archives but has sparked controversy about the responsibilities which then ensue.

An added change to the role of twenty-first century national archives is that they may now no longer be the obvious place of custody for material which crosses international borders. Globalization and improved communications has led to world wide organizations such as the United Nations and its various branches as well as commercial businesses which know no boundaries. Thus while

international diplomatic activity may be on record in the national archives the decisions to which they relate may well not be part of the official record, bringing a further dimension to the search for archival sources.

Turning to the question of material which is held in many national archives, but which might not be expected, is also interesting. The issue of the custody of private archival material in national archives is one which has generated considerable debate. The theory that national archives exist for purely administrative material is fine on paper and is often adhered to more strictly by national archives which have been established relatively recently such as Cyprus or Sweden. In practice, it is often less easy to distinguish between the official material and that which is frequently generated by individuals in the course of their duty. Additionally, for many countries the national or state archive may be, or have been in the past the only available repository for private papers. In Scotland the National Archives holds a considerable number of family, legal, and estate papers; and records of businesses, societies, and institutions. In Cuba the holdings cover all those papers that relate to a civil society including papers of those who contributed to cultural and political life. In Canada the remit of the Library and Archives is so wide that they solicit every type of material from Canadians on their Web site—"Anyone who feels that they have valuable materials, whether published or unpublished, and regardless of media, is encouraged to offer them to Library and Archives Canada (LAC)."^[15] This sort of statement is powerful in creating a national vision and the new title chosen by the Canadians—"Library and Archives Canada"—indicates the inclusiveness of their collecting policy; *Directions for Change* states that the combined organization "will play a significant role in the government of Canada and within the library, archival, cultural heritage, and learning communities in Canada."^[16] In India too it is recognized that the rich collection of private papers, acquired through donation or gift, and held in the National Archives complements the public records. Elsewhere some limitations are imposed such as in Australia where the private paper holdings are limited to those of prominent people such as governors-general, prime ministers, ministers, secretaries, and High Court judges. Indeed, to clarify the scope of their holdings the Web site of the National Archives of Australia specifies what it does not hold, and presumably will not accept. This includes information on convicts, on colonial migration, on nineteenth century Australian history including exploration or colonial administration, land title or settlements and records of births, deaths, and marriages. In England, although the National Archives has some private papers deposited in earlier periods, the policy is to encourage potential depositors to select another, more appropriate archive.

Legal papers are frequently part of the holdings of national archives although not specifically administrative

documents relating to government. In Portugal, the National Archives has oversight of the district archive services to which the records of civil registration, the courts, and the notaries public must be transmitted. In the Caribbean, legal holdings are part of the material held in the Bahamas and in Latin America, judicial material from the sixteenth century is kept in Ecuador, and the records of tribunals from about a century later in Argentina. In Europe, the National Archives of the Czech Republic holds judicial records as does the National Archives in Hungary which emphasizes the importance of many of the judicial papers of the second half of the twentieth century as an essential part of the history of a turbulent era.^[17] In Scotland, the National Archive holdings include legal records such as registers of deeds and land holdings (seisins), Chancery records, and adoption records leading to considerable use of their legal search room by lawyers. In England, the judicial exhibits produced as evidence in law courts and now held in the National Archive constitute a wonderful rag bag of items, hardly archival but adding much substance to similar legal reports. In Iceland, the records of the Supreme Court are regarded as public records and are transferred accordingly to the National Archives.

Ecclesiastical documents are another category of archive frequently found in national repositories though not within the strict definition of such organizations. In many cases this is due to historical accident, since the national archive may have or have had a wide remit as the only obvious place of safe deposit. This is often the case where the church in earlier periods acted as part of the civil administration, registering baptisms, marriages, and burials and providing the mechanism for proving wills. The necessity for court proceedings associated with the latter resulted in a need to ensure that documents were kept and often copied for safety; in England, the records of the Prerogative Court of Canterbury (testamentary court of the Archbishop of Canterbury) are available at The National Archives and form a valuable source for family historians. In Luxembourg, the archives of the Hospice of St John with genealogical information as well as evidence of the activities of the church from the thirteenth century are maintained in the National Archives. In Portugal, an extensive archive of ecclesiastical material is held in the National Archive of Torre do Tombo including diocesan and monastic papers.

Private papers, legal reports, and ecclesiastical documents all form part of many national archives but the twentieth century brought the advent of material in other formats—photographs, tapes, film, and electronic formats. In some countries these are accepted as any other deposit of selected archival material; the National Archive and Record Administration (NARA) in the United States multimedia collections include nearly 300,000 reels of motion picture film and more than 200,000 sound and video recordings. In Australia, as in some other countries, the

audiovisual holdings comprise not only those produced by government (200,000 film and video items), but also audiovisual material from Australian Broadcasting Corporation (ABC), Film Australia, Australian Film, Television and Radio School (AFTRS), Special Broadcasting Service (SBS), Defense, and many other government agencies. In other national archives such as Malta, Kenya, Costa Rica, and Yemen such collections, though smaller, are an essential part of the history of each country since audiovisual material, especially television footage, may be the only archival material which survives for some twentieth century events. Not all national archives contain audiovisual archives, however, partly due to the specialized nature of the material; in England the British Film Institute acts as an agent for The National Archives and the BBC maintains its own archive. Practical considerations make this a more convenient arrangement, obviating the need to maintain the facilities for viewing such material in the National Archives and ensuring that the collections are looked after by specialists. Elsewhere the broadcasting organizations also often maintain their own archival material, particularly commercial firms. In Thailand, by contrast, the government is planning to establish the Royal Private Film Archive as the place to preserve the King's moving and still pictures. The Coordinating Council of Audio-visual Archive Associations (CCAAA) which was established by UNESCO in 2001, has recommended that "Deposit conditions should apply to publicly funded archives with recognised national responsibilities and should apply to both commercial and noncommercial productions,"^[18] but it is not specified which organization this should be and it will undoubtedly vary according to circumstances.

Scope of National Archive Activity

If the scope of the holdings of national archives is diverse then the scope of the activities undertaken worldwide under this aegis is even more so. The description which each organization gives itself is revealing: some call themselves national archives and leave the interpretation to a vision statement, often backed up by a mission statement—for example the National Archives of Scotland or of Brazil; others include records management in the title to indicate a greater than just historic role, such as the National Archives and Records Administration of the United States of America; others use the term National Archive Services such as the Botswana National Archives and Records Services, or National Archival Services in countries such as Norway where the term encompasses a wider range of archive institutions than simply the designated national institution. The word "services" is used increasingly, documenting a global perception that while the historic archive must be maintained in its own right as a record of events, it is also imperative that every archive, whether national or other, serves the citizens of the country in which it is situated in a number of spheres.

A survey of Web sites on which national archives identify their *raison d'être* makes it clear how diverse these activities can be. In India, their vision is to help in spreading a feeling of national pride in the documentary cultural heritage and ensuring its preservation for posterity. The National Archives is concerned to develop the best means of conserving the records, to foster good relations between archives both at home and abroad, to increase access, and develop greater professionalism amongst creators, custodians and users. In the United States, the aspiration goes further with a vision that "all Americans will understand the vital role records play in a democracy, and their own personal stake in the National Archives."^[19] Although the title of the organization proclaims that they form the records administration arm of government, in the mission statement it is not explicitly stated, support for democracy, and the promotion of civic education being more prominent. In Kenya, the National Archive is clear that it has a vision to excel as an archives service in the view of all Kenyans and to serve as the Memory of the Nation; the Web site cites the overall activities of the service, which are common to many countries in the world, as continuing to

- Advise public offices on proper records management.
- Select valuable records for permanent preservation as archives.
- Store and preserve archives in the repositories.
- Publicize availability of information resources in our custody through computerization of indexes, digitization, World Wide Web; and through use of other communications and information technologies.
- Promote access to public records and archives for reference and research purposes, or just for leisure and enjoyment.^[20]

The Australians manage to encompass some philosophy about their approach to record keeping in their mission statement, referring to best practice in management from the point of creation and their concern to develop, manage, and promote a visible, known, and accessible national collection. This argues a confidence which is also visible in the statements issued by the Malaysian National Archive with a vision of molding a knowledgeable nation that values its national heritage, and a rather simpler mission which repeats the overall purpose of all national archives namely acquisition, conservation, and preservation but also includes popularizing the archives and national heritage and making the National Archives a resource and research centre. This introduces an academic element which is shared among some other national archives, such as Greenland, suggesting links to higher education. Finally, in the Netherlands another issue is explicitly raised, that of wishing to play a leading role in archive policy and to advise the State Secretary effectively, a point followed in the mission statement of The

National Archives in the United Kingdom where that is developed into information management—"The National Archives is at the heart of information policy—setting standards and supporting innovation in information and records management across the United Kingdom, and providing a practical framework of best practice for opening up and encouraging the reuse of public sector information."^[21]

It is clear that national archives fulfill a number of roles many of which are very similar and have been so for some time. Other roles are being developed not least on account of the dual role of preserving the past for the future but also ensuring that current records, increasingly in electronic format, are properly managed. Some, such as the State Archives of China, divide their activities, and their premises and staff, so a clear distinction is made between the two roles; others run a multifaceted operation connecting the past and the present with a view to ensuring the survival of it all for the future. Much depends on the scale of the organization and available funding; in a few countries large sums of private money supplement government support, but for defined purposes. The obvious example is that of the presidential libraries in the United States which are administered by the National Archives and Records Administration but with private endowments. Elsewhere the more modest official sums available require archives to bid for exterior funding to support digitization programs or even basic improvements to buildings and storage areas. In areas of the world where the workforce constitutes the major part of the annual expenditure all effort will be put into reducing that to a bare minimum; elsewhere the limiting factor may not be the size of the workforce but the untrained element.

CONCLUSION

National archives are a defined but diverse group, carrying out both basic and more advanced archival work on behalf of governments. The scope of what they do is limited by resources and by the type of national archive system, as well as the national perception of the role of archives in modern society. The diversity is important as it reflects the differing characteristics of each country, historic, legal, and cultural factors, and, as recognized by the EU, "it

would be inappropriate even to contemplate a 'model' of a National Archives service."^[22] If that is true for the EU, it is equally applicable to other areas of the world, let alone impossible to impose. Much of the value of national archives is contained in what each can offer to its very varied citizens.

Biological Resources Division, U.S. Geological Survey, Reston, Virginia, U.S.A.

Abstract

The United States National Biological Information Infrastructure (NBII) is a collaborative program with the mission of improving online access to the country's information about its biological resources. Coordinated by the Biological Informatics Program Office of the U.S. Geological Survey (USGS), the NBII provides a distributed infrastructure for scientific information provided by national, state and local governments, universities, museums, private organizations, and international collaborations. Concentrating on the fields of biodiversity and ecology, the NBII's main audience is considered U.S. land managers, scientists, and policy makers, but specific programs also support educators as well as private citizens. The NBII catalogs and links to data and information resources, provides searches of Web sites, develops tools for the integration and display of data, and synthesizes the latest information on select subjects; it also supports the development and use of standards and technological tools. The NBII is the only organization within the United States with the mandate and experience to organize and deliver the depth and breadth of biological information to the people.

INTRODUCTION

The U.S. NBII (<http://www.nbii.gov>) is a broad, collaborative program to make accessible online the nation's biological data and information, especially in the fields of biodiversity and ecology. The NBII includes over 250 agencies and organizations, with coordination and program management provided by the Biological Informatics Program of the U.S. Geological Survey (USGS). Because biological information comes from numerous public and private partners, and is found in multiple formats (e.g., datasets, maps, documents, and images), pooling these resources is a significant management and organization challenge. Many individuals and organizations, however, have recognized the value in discovering otherwise hidden information, in having rapid access to new data, and in data integration; this recognition has driven the formation and operation of the NBII over the past 15 years.

Calls began in 1993 for a national, digital system "to collect, house, assess, and provide access to the scientific information needed to understand the status of the nation's biological resources, the trends in the changes of that status, and the causes of those changes."^[1] Digital system initiatives already were underway for genomic, medical, and molecular information, and various government agencies, universities, and other organizations felt that an infrastructure was needed for biodiversity and ecological information. These calls led to the creation of the original NBII within the U.S. Department of the Interior (DOI) in 1994. The NBII initially focused on developing standards

and infrastructure to support the linking of specific data and information. Further calls for the expansion of the program, to a "next generation" NBII (p. 30),^[2] yielded a viable, distributed infrastructure for linking and providing a wider breadth of information online.

The current NBII seeks to meet information needs defined by the U.S. government, by NBII partners, and by outside users, which include researchers, resource managers, policy makers, educators, students, and others. Its efforts emphasize credible, scientific information from the government agencies (federal, state, and local), museums, university collections, gene banks, nongovernmental organizations, botanical and zoological gardens, libraries, bibliographic services, as well as other sources. The NBII has four approaches to gather and disseminate information from these disparate sources: 1) improving standards and technology; 2) working with various regions to meet local information needs; 3) supporting data sharing on national or global issues (e.g., invasive species); and 4) creating the network for integrating local to global knowledge. The resulting infrastructure has both centralized and distributed components: the NBII National Program Office at USGS maintains the standards and protocols, a data repository, a search engine, and Web sites; and distributed offices feed in data from various sources and support specific information portals. Both the Program Office and the distributed projects also help develop tools to synthesize, integrate, and apply biological information.

Overall, while the NBII's general mission has remained relatively constant since its inception in 1994, it has grown

with the opportunities afforded by new technology and with new partnerships from local to global levels. The next section addresses the history of the NBII, as well as its mission, goals and strategy, and its organizational structure. The NBII's extensive and complex relationship to other organizations is discussed in sections for Regional Foci, Thematic Foci, National Standards and Technology, and Knowledge Integration.

HISTORY

Throughout American history, many leaders and agencies have recognized the value of information on its biological resources. Shortly after the United States was formed, Thomas Jefferson charged Meriwether Lewis with gathering knowledge about the landscape, soil, plants, and animals of the West during the Lewis and Clark Corps of Discovery trip to the Pacific Ocean.

Your observations are to be taken with great pains & accuracy, to be entered distinctly, & intelligibly for others as well as yourself, to comprehend all the elements necessary...^[3]

Lewis collected extensive field notes and specimens during the 1804–1807 trip. In the two centuries that have followed, hundreds of local, state, and federal agencies and projects, universities, museums, and private citizens have amassed huge amounts of diverse data and information. Unfortunately, there has been no overarching plan to organize and make these disparate collections accessible. The NBII was created to help find and serve information about our nation's biological resources.

The origins of the NBII can be traced, if not to Jefferson, then at least back to a 1993 report by the National Research Council (NRC), titled “A Biological Survey for the Nation.”^[1] In this report, the NRC recognized the value of interoperability and of linking disparate information types from distributed sources via the Internet, thus providing better and quicker access to scientifically reliable information on biological resources. The NRC recommended that the DOI create a “National Biotic Resource Information System” (NBRI) that would develop new methods to collect and distribute data and information about data, as well as promote standards to ensure compatibility among information sources. The NBRI would especially support database development and coordination at local, regional, and national levels. To help address the multiple issues identified in the NRC report, including that of information management, the U.S. Secretary of the Interior Bruce Babbitt created the National Biological Survey (NBS) within the DOI in 1994; the NBS included the NBRI as one of its major components. The NBS was later renamed as the National Biological Service.

The following year, President Clinton signed Executive Order 12906^[4] and created the National Spatial Data Infrastructure (<http://fgdc.gov/nsdi/>) to coordinate acquisition and access to geographic data. In recognition of the parallel objectives of the NSDI and the NBRI, Secretary Babbitt renamed the NBRI to the “NBII.” The NBII began work early on standard vocabularies in order to interlink data and information. An initial focus of the NBII was to assist the NSDI by writing the Biological Data Profile of the Federal Geographic Data Committee (FGDC) Metadata Content Standard. Metadata is information that describes data and datasets, (both geospatial and non-geospatial); this standard carries both metadata and actual data content, such as specimen descriptions. The NBII also joined the partnership for the Integrated Taxonomic Information System (ITIS; <http://www.itis.gov>), an authority for organism names and taxonomy, and supported development of the National Vegetation Classification Standard, part of a collaborative program between the USGS and the National Park Service.

In 1996, the entire NBS was folded into the USGS and was renamed the Biological Resources Division (BRD); the Office of Biological Informatics and Outreach (OBIO, which later would become the Biological Informatics Program) of the BRD then became the official coordinator of the NBII. Work continued on standards, on building partnerships, and on building Web sites to disseminate information. This work resulted in a number of awards, including the 1997 APEX Award, the 1999 Government Technology Leadership Award, Best Feds on the Web (1999); and the 1998 and 1998 Renew America National Awards for Environmental Sustainability.

Over the next few years, more entities and organizations expressed the need to expand the NBII to meet the initial mission as proposed by the NRC. In 1998, the Biodiversity and Ecosystems Panel of the President's Committee of Advisors on Science and Technology (PCAST) provided strong support. The PCAST reiterated the role of the NBII in society in a report to President Clinton titled “Teaming with Life: Investing in Science to Understand and Use America's Living Capital.”^[2] The cover letter by John A. Young's states “The PCAST report provides a roadmap to bringing the vast advances in information technology to the field of biodiversity in order to develop a ‘next generation’ national biological information infrastructure. Such capacities will allow researchers and resource managers worldwide to make full use of information generated on ecosystems and biodiversity.” The PCAST proposed the most suitable configuration for this “next generation NBII” as being a distributed system of data sources, complemented with multiple entry points, or “nodes.”

The PCAST report was the decisive factor, and in 2000, the U.S. Congress appropriated funds for the development of a NBII node-based infrastructure. In 2001, the NBII initiated two thematic and six regional nodes, including the

Fisheries and Aquatic Resources Node (<http://far.nbii.gov>), and the Pacific Northwest Node (<http://pnwin.nbii.gov>). These nodes identify, compile, and disseminate information by working with partners associated with a specific region, issue, or research data need. Today, there are eight regional nodes and four thematic nodes, along with similar, smaller projects, as discussed in more detail below.

The new node structure brought additional local and national partners into the NBII. The thematic work, however, as well as the NBII's continued work with standards, meant that the NBII also needed to develop strong ties with international entities. In 2001, the NBII began a formal collaboration with the Global Biodiversity Information Facility (GBIF; <http://www.gbif.org>), an international effort to meet the framework of the Rio Convention on Biodiversity, which proposed a worldwide information and data exchange, as well as training in informatics for developing countries. One objective of GBIF, with which the NBII has close coordination, is to provide a global, online infrastructure for primary biodiversity data, especially museum specimen information. The NBII helped support the standards and protocols needed for this broad effort, and became the U.S. representative and the U.S. node of GBIF. Beginning in 2002, the NBII also began helping the NATO Information Management Committee of the NATO Research and Technology Agency with the design of the NATO Science, Research, and Technology Network (STARNET), and the International Council for Science (ICSU) recognized the NBII as the U.S. World Data Center for Biodiversity and Terrestrial Ecology. In 2003, the NBII helped launch the Global Invasive Species Information Network (GISIN; <http://www.gisinet.org>). That same year the NBII also became a leading member of the Inter-American Biodiversity Information Network (IABIN; <http://www.iabin.net>), which helps coordinate and network biodiversity information from the Western Hemisphere, and it helped launch the IABIN Invasives Information Network (I3N) search system (http://i3n.iabin.net/search/mercury_search.html). The NBII has continued to join in other international information partnerships, such as the Conservation Commons.^[5]

Today, the NBII partnership includes more than 250 agencies and organizations contributing their expertise, data, equipment, facilities, and labors directly to create and support standards, to strengthen the NBII infrastructure, and to increase the pool of accessible information.

MISSION, GOALS, AND STRATEGIES

The current NBII mission is similar to its original mandate and is defined as *providing the nation with a mechanism for accessing the vast amount of existing biological and natural resources data, information products, and analytical tools that support and enhance science-based decision-making.*^[6]

The NBII mission encompasses all biological and natural resource data and applications for the nation, a very complicated task requiring wide coverage from molecular work and genetics, to species interactions, to biomes, to related resource information such as water and geology. Thus, the NBII Steering Team formulated its Strategic Plan^[6] from the plans of both the DOI and the USGS Biological Informatics Program in which the NBII is housed, and from input from multiple parties, including NBII partners, other stakeholder groups, and Congress. These groups specifically requested ecological information to support a “better understanding of current environmental conditions, develop predictions about the future, and provide options for adopting a course of action or response to these conditions (p. 1).”^[6] The NBII thus focuses on three knowledge domains: 1) species information, including biosystematics and nomenclature, habitat requirements, and population dynamics; 2) landscape level information, including land, vegetation, and water classifications and status; and 3) the environmental drivers behind trends in invasive species, wildlife diseases, climate change, and human impact.

The NBII's methods of information management fall within the science and practice of “biological informatics,” or “bioinformatics,” which creates and utilizes techniques for compiling, linking, organizing, storing, integrating, synthesizing, and delivering biological data and information, as well as tools to help analyze and apply this information. The terms bioinformatics and biological informatics often have been used more narrowly to denote biomolecular information only, but both terms actually address all scales of biological data from the molecular to ecosystem levels.

For each of these knowledge domains, the NBII has four main goals (p. 8).^[6]

- Develop the framework to support knowledge discovery and creation for the nations' biological and ecological resources.
- Create an integrated library by systematically discovering, acquiring, organizing, storing, updating, and making available scientific data and information from diverse sources. Ensure that this library responds to the information needs of land and resource managers and other stakeholders and users.
- Lead the development, selection, and distribution of tools and standards necessary to facilitate system-wide interoperability and allow meaningful interactions with scientific data and information.
- Empower NBII users by creating an awareness of the NBII and its capabilities and providing support to enable users to directly apply NBII products and services within their own areas of concern.

To meet these goals, the NBII coordinates with the many other organizations that have developed similar regional or thematic interests and resources. Consequently, a web of

projects and funding has emerged. Recently, funding for NBII operations has been flat or declining (p 132),^[7] and much increasing in-kind work through partnerships is critical for the NBII to meet its goals. For example, according to a 2005 DOI Investment Overview,^[8] partners provided the equivalent of \$3 for every one the NBII spent in 2002. This funding and leveraging environment influences the projects on which the NBII can focus. Many pressing national concerns, however, are not fully met under the current funding regime. For example, most natural history collections are not digitized and remain inaccessible over the Internet.

Organization

The NBII is managed by the Biological Informatics Program of the USGS, based in Reston, VA, and is led by the NBII Steering Team, consisting of USGS employees (Fig. 1).

The figure shows how multiple groups provide input on information needs, goals, and objectives. One such group is the Biodiversity and Ecosystems Informatics Working Group (BioEco; <http://www.bioeco.gov>), established under the White House's Office of Science and Technology Policy in 1997 to improve the coordination of federal

biodiversity and ecosystem informatics activities. The NBII also receives input directly from the scientific communities through staff who attend scientific meetings and participate in discussions with outside scientific committees and associations. Finally, the hundreds of partners in the NBII federation provide input either directly to the Steering Team or via project managers.

In building the national infrastructure, the NBII has four organizational approaches: national themes, regional foci, network standards and technology, and knowledge integration. Staff within the thematic and regional foci concentrate on discovering, incorporating, and integrating data specific to a region or theme, as well as in creating application tools. The Network Standards and Technology and the Knowledge Integration groups assist in this process, but also provide overarching standards, tools and applications, and technical support for all NBII Web sites and repositories. Many project managers and staff are based at a USGS or partner science centers that specialize in their subject, such as the USGS Center for Biological Informatics (CBI) in Denver, CO, while additional Program staff are based in Reston; project managers within each approach, however, commonly work closely with managers in others, in person or remotely. The main projects within each approach are detailed below.

Fig. 1 Organization of the NBII's activities.

Source: Modified from Ruggerio, M.; Marcia McNiff, M.; Olson, A.; Wheeler, B. Strategic Plan for the U.S. Geological Survey Biological Informatics Program: 2005–2009; U.S. Geological Survey, Biological Resources Discipline, 2005; 1–22, http://www.nbii.gov/images/uploaded/8496_1178901646922_BIO5yrPlan.pdf (accessed March 15, 2008).^[9]

Regional Foci

Data issues and collections often have a geographical basis and orientation, thus information users often seek a regional approach to sharing data. A NBII regional focus, or “node,” includes local and regional partners who work with a NBII regional manager to help determine the data priorities for that region, and then to develop, acquire, and manage that content. The resulting Web site within the NBII system provides an entry point to that regional data and information, which also becomes accessible to the general NBII user community through the main NBII Web site and overarching tools. Eight regions currently have projects underway, and the strategic plan calls for the implementation of 12 nodes to effectively blanket the country (Fig. 2; Table 1).

Different regional nodes can have different subject and resource foci, depending on their partners’ needs. The Pacific Northwest Information Node (PNWIN; <http://pnwin.nbii.gov>) makes available information about forests, as well as other subjects. The Southern Appalachian Information Node (SAIN; <http://sain.nbii.gov>) was one of the first nodes to form, and it combines information and resources to improve productivity, resource management, and sustainable development within its region. An example SAIN project includes assisting the Appalachian State University in developing a Southeast Herbaria Network to support the digitization of and improved access to botanical collections. A more recent formation, the Mid-Atlantic Information Node (MAIN; <http://main.nbii.gov>) provides online access to biodiversity information about the Chesapeake Bay area, as well as expanding into other subjects.

National Themes

Many environmental issues are relevant in a majority of regions. To help research and decision-making on these issues, the NBII provides a layer of national-level coordination by constructing several major thematic information nodes: Bird Conservation, Wildlife Diseases, Invasive Species, and Fisheries and Aquatic Resources. It also manages smaller thematic projects, such as collecting information on Amphibians, Botany, and Pollinators.

Table 1 Regional nodes of the NBII.

Regional node	States
<i>Active nodes</i>	
California	California
Central Southwest/ Gulf Coast	Arkansas, Louisiana, Oklahoma, and Texas
Mid-Atlantic	Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia
Mountain Prairie	Kansas, Montana, Nebraska, North Dakota, South Dakota, and Wyoming
Northeast	Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, and Vermont
Pacific Basin	Hawaii, Guam, and the island nations of the Pacific
Pacific Northwest	Idaho, Oregon, and Washington
Southern Appalachian	Alabama, Kentucky, Mississippi, and Tennessee
<i>Future nodes</i>	
Alaska	Alaska
Great Lakes	Illinois, Indiana, Iowa, Michigan, Minnesota, Missouri, Ohio, and Wisconsin
Southeast	Florida, Georgia, North Carolina, and South Carolina
Southwest	Arizona, Colorado, Nevada, New Mexico, and Utah

Source: Strategic Plan for the U.S. Geological Survey National Biological Information Infrastructure (NBII) July 2005; National Biological Information Infrastructure: Reston, VA, 2005, http://www.nbii.gov/images/uploaded/8496_1165236262413_NBII_Strategic_Plan.pdf (accessed March 15, 2008).^[6]

Examples of the focal work conducted within a node can be seen in the Invasive Species Information Node (ISIN; <http://invasivespecies.nbii.gov>), which integrates invasive species data at a national level and which supports real-time and predictive modeling, species identification, and early warning. For example, the ISIN is working with the National Invasive Species Council and federal agencies to develop a national framework for Invasive Species Early Detection and Rapid Response (EDRR). Like most nodes, the ISIN has major partners; among them in this case are the Nonindigenous Aquatic

Fig. 2 The NBII regional foci, or “nodes.”

Source: Strategic Plan for the U.S. Geological Survey National Biological Information Infrastructure (NBII) July 2005; National Biological Information Infrastructure: Reston, VA, 2005, http://www.nbii.gov/images/uploaded/8496_1165236262413_NBII_Strategic_Plan.pdf (accessed March 15, 2008).^[6]

Species Project of the USGS Florida Integrated Science Center, and the National Institute of Invasive Species Science at the USGS Fort Collins Science Center. Another example of the NBII's thematic work is the Wildlife Disease Information Node (<http://wildlifedisease.nbii.gov>), which helps operate the Chronic Wasting Disease Data Clearinghouse and is helping build the National Highly Pathogenic Avian Influenza Early Detection Data System.

National Standards and Technology

The remaining two NBII organizational approaches, Network Standards and Technology, and Knowledge Integration, help provide the means to link to and serve all the information from various partners.

Interlinking data and information depends in part on a common vocabulary, or standard. Scientists use different techniques for research and thus original data differs in the types and scales of measurements. Supplying metadata provides an opportunity to document the resource (e.g., dataset, information product, tool, etc.) with a common vocabulary. This way, researchers know what they are comparing, and thus can implement conversions if necessary. Metadata also adds value by supplying keywords and information about provenance, quality, timeliness, and authority.

As previously mentioned, one of the first projects of the NBII was to create the FGDC Biological Data Profile (<http://www.fgdc.gov/standards/projects/FGDC-standards-projects/metadata/biometadata/>). Work also continues in support of ITIS and the Vegetation Mapping Classification. Other work in standards includes

- *The Biocomplexity Thesaurus* (<http://thesaurus.nbii.gov/>)—an online thesaurus of scientifically reviewed biological terms and preferences for use. Begun in 2002, the NBII develops and maintains the thesaurus in partnership with CSA (previously known as Cambridge Scientific Abstracts). It includes over 15,000 terms on subjects such as aquatic sciences and fisheries, life sciences, pollution, social sciences, ecotourism, and, now incoming, fire ecology, and management.
- *The Darwin Core* (<http://wiki.tdwg.org/twiki/bin/view/DarwinCore/WebHome>)—a derivative of the Dublin Core standard, the Darwin Core deals specifically with natural history museum specimens and other primary species data. In partnership and with support from the NBII, the Biodiversity Information Standards (until recently known as the Taxonomic Databases Working Group; TDWG; <http://www.tdwg.org>) develops Darwin Core and similar standards.
- *The Geospatial Interoperability Framework* (http://www.nbii.gov/portal/community/Communities/Toolkit/Geospatial_Framework/)—a data strategy to reduce development time for geospatial applications, based on the International Standards Organization (ISO)

standards and the Open Geospatial Consortium (OGC) specifications. It is integrated with other core NBII Framework standards and protocols, such as the Universal Description, Discovery and Integration (UDDI) protocol.

The NBII continues to create or adopt, and then implement new standards, such as for ecological datasets, multimedia resources, and observational records. The NBII also is investing in the development of semantic Web technology for biological data through Spire (<http://spire.umbc.edu/>) and others entities, allowing the linking of common terms and scientific concepts.

In addition to standards, many activities within the NBII require technological support. The CBI, which is also managed by the USGS Biological Informatics Program, provides a significant portion of this technical support. It houses the majority of the servers, supplies the security, provides Web services, researches new bioinformatic techniques, and helps create protocols, tools, and applications. Further, the NBII provides technological support to partner systems, for instance, it houses a mirror of the GBIF's data.

Knowledge Integration

The NBII accesses data and information from a variety of organizations. Its mandate is to compile and, where possible, to facilitate the integration of this data and information in order to support the discovery, comparison, and use by a wide variety of users. The NBII provides information directly to individual users through its Web sites, search engine, and other tools; it also shares information with research institutions and other agencies, with organizations that help compile, integrate, and synthesize information, and with other distributed networks that help feed data from multiple organizations (Table 2; see http://www.nbii.gov/portal/community/Communities/Toolkit/NBII_Partners/ for a complete list). The level of integration depends on the format of the data, customer needs, and the technology on hand.

The objective of NBII knowledge integration activities is to bring together scientifically credible data and information in a manner that not only maintains attribution, provider ownership, and the integrity of the data, but also adds value by applying standards and by providing further, similar data resources. This objective is a challenge in light of the great variability in information and in source organizations. Many suppliers do provide information available in preset, standardized formats, easily served by the NBII through a catalog or other appropriate means. More often, however, information suppliers with different base infrastructures serve the NBII with collections of varying sizes and in different formats, including record-level databases, datasets, maps, images, documents, and

Table 2 Sample NBII data and information partners.

U.S. federal government	U.S. local and state governments	Nonprofits	Universities	Multisector and international
U.S. Fish and Wildlife Service	California Department of Fish and Game	Conservation International	University of California	International Ocean Biographic Information System
U.S. Bureau of Land Management	Colorado Division of Wildlife	Ecological Society of America	City University of New York	FishBase
U.S. Department of Agriculture	Illinois Department of Natural Resources	Natural Science Collections Alliance	Colorado State University	Global Biodiversity Information Facility
USGS Gap Analysis Program	New York City, Borough of Queens	Association of Fish and Wildlife Agencies	Appalachian State University	CBD Clearing-House Mechanism
Smithsonian Institution	Chattanooga-Hamilton County Regional Planning Agency	Bernice Pauahi Bishop Museum	Columbia University, Earth Institute	Eastern Brook Trout Joint Venture
Greater Yellowstone Coordinating Committee	Galveston Bay Estuary Program	Appalachian Trail Conservancy	Boise State University, Raptor Research Center	BirdLife International
U.S. Department of Energy	Wyoming Game and Fish Department	NatureServe	Cornell University	Global Invasive Species Programme

species lists. Thus, the NBII must find and apply multiple, flexible integration methods. Furthermore, the act of integration may reveal gaps in the information, and the NBII may then support initiatives to gather the missing data. Finally, in many cases, the methods to gather or integrate biological information may be difficult to use or nonexistent; thus, the NBII also develops new protocols, data processing programs, and other tools to assist in data integration.

The NBII has multiple knowledge integration activities: the key activities are the cataloging of information sources, data harvesting from multiple servers and indexing them in one location, the hosting of collections, the coordination of experts, and the provision of platforms through which the information can be accessed.

Catalogs and Collections: The identification, prioritization, description, and linking of important data and information sources is the first step in integrating information, and has been a NBII focus for the past several years. The NBII's regional and thematic operations describe and document data resources using the NBII Resource Catalog standard, which aids in searching these resources from any NBII Web site. Other multiagency partnerships contribute to specialized catalogs or data collections that are also served through the NBII's search portal, including

- *The NBII Metadata Clearinghouse* (<http://mercury.ornl.gov/nbii>)—a program of the NBII and the U.S. Department of Energy's Oak Ridge National Laboratory in Tennessee. The Clearinghouse provides detailed descriptions of thousands of biological data sets.
- *The Natural Resource Monitoring Partnership (NRMP)* (<http://nrmp.nbii.gov>)—provides Web-based tools developed by the NBII for the NRMP. These

tools are for sharing natural resource monitoring project locations, and a library of monitoring protocols.

- *The NBII LIFE* (<http://life.nbii.gov/>; recently known as the NBII Digital Image Library; <http://images.nbii.gov>)—a growing, searchable collection of images related to nature and the environment. A variety of NBII partners contribute the images and detailed metadata about those images. This library is also setting up harvesting mechanisms with other image libraries that have similar metadata.

Harvesting Partner Sites: The NBII's partners help provide biological data and information such as abstracts, databases, species pages and lists, and maps. The NBII constructs software programs to “crawl” the partner sites, and the partner provides services that help open hidden or blocked information, or to make the process easier. Examples of the information exchanged include species pages from NatureServe, datasets from the Long-Term Ecological Research (LTER) Program, and reports from the UNESCO Man and the Biosphere programme (MAB). The NBII also links to national and international collections networks such as the Mammal Networked Information System, MaNIS (<http://manisnet.org/>) and HerpNet (<http://www.herpnet.org/>), a global network of herpetological collections data. Finally, the NBII is partnering with other major informatics initiatives, for example, within the fields of hydrology and geology, to share information.

Web Crawling: The NBII also uses software to crawl public Web sites. A NBII staff member first researches a site, such as the U.S. Fish and Wildlife Service (<http://www.fws.gov>), and constructs a software program to crawl the site, called a “spider.” The spider starts at a designated page, copies it, and then crawls the hyperlinks

from that page to the next set of pages, and so on to a depth set by NBII staff. Exception lists are generated for each site to exclude irrelevant information. As the crawler returns Web pages, available metadata is attached, and the pages then are served through the NBII. Crawling has some drawbacks, but the NBII is dedicating staff to refining the process.

Hosting: The NBII provides infrastructure to the data networks of selected partners such as ITIS, the Fire Research and Management Exchange System (<http://frames.nbii.gov>), and the Terrestrial and Aquatic Gap Analysis Program (GAP; <http://gapanalysis.nbii.gov>), a national program that integrates data on land cover, species distributions, and land stewardship to determine gaps in the protection of species. The NBII also hosts Web sites or provides other technological support for partners: it helped develop and maintains the U.S. Web site for IABIN, along with the I3N (<http://i3n.iabin.net>), and the I3N cataloging tool.

Expert Coordination: Within the NBII's regional and thematic activities, as well as within overarching projects, much effort is put into finding and enlisting the experts in a field, one of the best data resources available. The NBII brings together experts in workshops on critical topics and helps maintain expert directories, such as the Taxonomic Resources and Expertise Directory (TRED; <http://tred.nbii.gov>). The NBII also provides gateways to outside expert databases.

Collaborative Platforms: The NBII provides a password-protected virtual collaboration space, (<http://my.nbii.gov>), where one can join communities, find project-related documents have discussions, and share information in a dynamic, secure environment. Specific communities have been set up for projects such as the Appalachian Trail Environmental Monitoring Program and the Multistate Aquatic Resources Information Systems.

EXAMPLE OF THE FOUR APPROACHES

A good example of how the NBII applies the four different approaches to making biological information accessible is with the use of species occurrence data, especially museum collection information and observational records. Species occurrence data can be used by land managers, scientists, and policy makers to predict current, past, and future distribution of species; to identify biodiversity hot spots; to predict the impact of road construction; or to help model the impact of climate change. Museums and research institutions have long held historical records of occurrences, but this data has not been readily available over the Internet. Global Biodiversity Information Facility is now providing an online platform for serving such information. Through its regional and thematic projects, the NBII finds collections and catalogs them; it also helps recruit museums to join GBIF and make their museum

records available. As one necessary component, GBIF and the NBII assisted and helped support financially the development of the standards needed for data integration, including the Darwin Core, the FGDC Biological Data Profile, and species names from ITIS. Once the records at each of the thousands of museums are in a standard format, GBIF uses transport protocols to query and transfer the information over the Internet. The NBII and GBIF helped support development of these transfer protocols, including the Distributed Generic Information Retrieval (DiGIR) protocol currently in use, and now a protocol combining DiGIR and others, called TAPIR (<http://www.tdwg.org/standards>). The NBII sponsors two to three workshops a year on the implementation of DiGIR protocols. Finally, the NBII also assists with the development of geospatial applications, such as the Geospatial Interoperability Framework, in order to help provide a common platform for serving the collected information from thousands of providers.

All of these activities extend past the U.S. borders. Through the NBII-GBIF partnership and other partnerships, the NBII provides global access to U.S. data and collections, representing them to the international community, but it also brings critical data directly back to the United States that is useful for investigating the impact of invasive species, climate change, and other environmental issues.

CONCLUSION

Knowledge about the biological world is critical to our health and prosperity, and best practices to ensure that information is organized and accessible are vital. Prior best practices concerned providing and storing handwritten copies, as Jefferson instructed Lewis:

Your observations are to be taken with great pains & accuracy, to be entered distinctly & intelligibly for others, as well as yourself, to comprehend all the elements necessary, with the aid of the usual tables, to fix the latitude and longitude of the places at which they were taken, and are to be rendered to the war office for the purpose of having the calculations made concurrently by proper persons within the U.S. s[sic]everal copies of these as well as of your other notes should be made at leisure times, & put into the care of the most trust-worthy of your attendants, to guard by multiplying them against the accidental losses to which they will be exposed. A further guard would be that one of these copies be on the paper of the birch, as less liable to injury from damp than common paper.^[3]

Today, information can be also stored digitally and made available over the Internet to a broad range of users, thus helping society make informed decisions about the use of our biological resources. The NBII attempts to discover, organize, and add value to information from the molecular level to the ecosystem level, and then disseminate it. To

accomplish this task it has developed partnerships with local, state, and federal agencies and well as intergovernmental bodies and private organizations. Because of the interconnectedness of the world's biological resources and the people within it, the NBII mission has come to include the coordination of information at a global scale. In so doing, the NBII has shepherded in a new global information network that has been recognized by distinguished scholarly and public panels as both incredibly successful and valuable.^[10–13]

The same government and private study groups, committees, and task forces have also recognized the huge challenges in providing access to our natural resource knowledge base, as well as acknowledging gaps in the knowledge we do have. The information that we now have through the NBII's efforts does not begin to approach the volume and diversity that we need to make informed decisions. The NBII will continue to face daunting challenges in the political, social, and technological spheres. Our demands for food, water, shelter, medicines, and energy require that we develop a much greater understanding of the biological world. Greater understanding can only be built on data and information that have been gathered over the centuries and are still being gathered. We can hope that society has the will and foresight to support the NBII to the degree necessary to accomplish this massive undertaking, since there is no other organization in the United States with the mandate and experience to address the breadth of the issue.

ACKNOWLEDGMENTS

Sincere thanks to Kate Kase, NBII Program Manager, Anne Frondorf, former NBII Program Manager, and Ron Sepic, NBII Information Liaison, for providing information upon request, and to Vicky Cooper, NBII Graphic Designer, for updating the graphics.

National Historical Publications and Records Commission (NHPRC)

Keith Donohue

*National Historical Publications and Records Commission, Washington,
District of Columbia, U.S.A.*

Abstract

The National Historical Publications and Records Commission (NHPRC) is the grantmaking arm of the National Archives and Records Administration, supplying financial support for projects that preserve and provide access to historical records of national significance housed in collections across the country. Each year, the NHPRC awards grants, based on its annual appropriations, to state and local government archives, nongovernmental archives, historical documentary editing projects, and other nonprofit organizations. It currently runs 10 grant or subvention programs and one fellow program. Since 1964, the NHPRC has awarded nearly \$175 million to some 4400 projects in all 50 states, the District of Columbia, and other special jurisdictions. As part of the National Archives, the Commission is chaired by the Archivist of the United States and governed by a 15-person advisory board, unique among Federal agencies since it includes appointees and representatives of all three branches of government—the Executive, Legislative, and Judiciary.

DOCUMENTING DEMOCRACY: THE NATIONAL HISTORICAL PUBLICATIONS AND RECORDS COMMISSION

The National Historical Publications and Records Commission (NHPRC) is the grantmaking arm of the National Archives and Records Administration, supplying financial support for projects that preserve and provide access to historical records of national significance housed in collections across the country. Each year, the NHPRC awards grants, based on its annual appropriations, to state and local government archives, nongovernmental archives, historical documentary editing projects, and other nonprofit organizations.

The National Archives serves American democracy by safeguarding and preserving the records of our Federal Government, ensuring that the people can discover, use, and learn from this documentary heritage. Continuing access to the essential documentation of the rights of American citizens and the actions of their government helps support democracy, promote civic education, and facilitate historical understanding of our national experience.

As part of the National Archives, the Commission is chaired by the Archivist of the United States. A 15-person advisory board serves as Commissioners, and they are charged with reviewing all of the applications and recommending projects to the Archivist which projects to fund. Unique among Federal agencies, the Commission is represented by all three branches—the Executive, Legislative, and Judiciary, as its members include two Presidential appointees and representatives from the Department of

State and the Department of Defense; a member from each house of Congress and a representative from the Library of Congress; and a representative appointed by the U.S. Supreme Court. Rounding out the advisory body are representatives from the professional societies of archivists, historians, documentary editors, and records administrators. An Executive Director, appointed by the Archivist, reports to the advisory board and manages a small administrative staff at the NHPRC offices in the National Archives headquarters in Washington, D.C.

Since 1964, the NHPRC has awarded nearly \$175 million to some 4400 projects in all 50 states, the District of Columbia, and other special jurisdictions. From the papers of America's Founding Era to contemporary electronic records, the NHPRC documents democracy, linking the records of the Federal Government with historical materials across the country. It awards grants through the following funding categories:

- *State and National Archival Partnership Grants* to build a national archival network by strengthening archives and historical records programs in each of the states. *Only state government agencies, or their designated fiscal agents, are eligible to apply.*
- *Digitizing Historical Records* to digitize nationally significant historical records collections and make the digital versions freely available on the Internet.
- *Electronic Records Projects* to support efforts that will lead to sustainable electronic records archives that preserve digital records with enduring historical value.

- *Professional Development Grants for Archives and Historical Publishing* to improve the training and education of professionals in the archival and historical publishing communities.
- *Strategies and Tools for Archives and Historical Publishing Projects* to develop new strategies and tools that can improve the preservation, public discovery, or use of historical records.
- *Archives—Basic Projects* to reveal “hidden collections” in archives by processing materials in backlogs.
- *Archives—Detailed Processing Projects* to conduct detailed processing and preservation of collections of national significance.
- *Publishing Historical Records* to publish historical records of national significance.
- *Publishing Historical Records—Founding Era* to publish the records of the Founding Era of the United States. *Open only to the previously funded projects dedicated to publishing the papers of John Adams, Benjamin Franklin, Thomas Jefferson, James Madison, George Washington, and records that document the Ratification of the Constitution and the First Federal Congress.*
- *Publication Subventions* to enable nonprofit presses to publish volumes of historical documentary editions. *Open only to assist publication of NHPRC-sponsored or -endorsed editions.*
- *Historical Editing Fellowships* to allow publications projects to host Historical Documentary Editing Fellowships. *Open only to NHPRC-sponsored or -endorsed publishing projects.*

A Brief History

Imagine a national archive double the size and scope of the National Archives. According to the 2004 National Archives and Records Administration Plan, traditional archival holdings total 2.9 million feet. Extrapolating data from earlier surveys, we estimate that state archives alone hold about 2.7 million feet. The mental jump is easy if you count state archives and records repositories which house the documentary heritage of governments from Alaska to Florida. This American archives increases exponentially when the hundreds of city and local government archives are added to the mass. Imagine the American archives connected to a Web of the many other private institutions, nongovernmental organizations, and community associations, home to billions of documents, images, recordings, and other clusters of information. *Where History Begins*, a 1998 report by the Council of State Archivists, estimated nongovernmental repositories held 4 million cubic feet. This *archives of archives* runs like a great river through our national consciousness: official government records at all levels providing the essential evidence for documenting our

political democracy, and billions of other records and papers complementing our understanding of our diverse history and culture.

En masse, the archives defeat every hope of completion. Archivists cannot save it fast enough; researchers cannot ever reach the bottom. Order is provisional, always. Selecting what to save, what to discard, and how to organize and make public the records embedded in the great American archives is the central challenge to all those engaged in documenting democracy.

The NHPRC is a mechanism within the National Archives and Records Administration for reaching out to and connecting thousands of archives, and records repositories across the country dedicated to preserving and publishing the primary sources of the American story in its many forms. For the past 45 years, the Commission has awarded grants to help strengthen the network of state government and local archives and to make public documentary materials in possession of the Government and those in private hands.

“National archives have a natural history of their own.” So wrote J. Franklin Jameson and the Assistant Committee on the Documentary Historical Publications of the United States Government to the Committee on Department Methods in its 1908 report. Their report laid out the case for a Federal program in conjunction with a National Archives, which would publish the documentary materials, whether issued by the Federal Government or not, that would “meet more fully the needs of the Government, of historians, of the public, and be a source of credit to the nation.” Commonly known as the Keep Commission, after its chairman, Charles H. Keep, the Committee on Department Methods was a panel appointed by President Theodore Roosevelt to review the efficiency of operations of the Federal Government. The Assistant Committee was chaired by historian Worthington C. Ford, and had as its members: Charles Francis Adams, Charles M. Andrews, William A. Dunning, Albert Bushnell Hart, Andrew C. McLaughlin, Alfred T. Mahan, Frederick J. Turner, and its Secretary, J. Franklin Jameson. The Assistant Committee’s full report can be found in *John Franklin Jameson and the Development of Humanistic Scholarship in America*, Vol. 3, The University of Georgia Press: Athens, Georgia (2001), pp. 56–71.

Jameson and his fellow historians had been gently twisting the government’s arm for some time. One of the first tasks undertaken by the American Historical Association after its founding in 1884 focused on the need for a national archival system, and as early as 1891, calls went out for a commission empowered to publish the national record. The natural history of the archives and a national publishing program evolved slowly. Fifty years after the call, the answer finally came with the establishment of the National Archives and the National Historical Publications Commission.

As envisioned by Jameson, the national program would support publishing of two classes of documentary materials:

The one class consists of lists, inventories, indexes, and calendars in the exact or restricted sense of that term, which are intended to serve the officials and the public as finding-lists or guides to the materials kept in the official repository. . . . The other is that of publications which consist of documents printed at full length, such as the Journal of the Continental Congress, the Official Records of the War of the Rebellion, the old American State Papers, or almost any other of the historical publications of the American government. It is submitted that the main question with respect to such a plan is, What collections of material hitherto unprinted are most needed in order that the history of this country may be elucidated to its citizens?

—MEMORANDUM respecting the organization and administration of the proposed National Archives, by J.F. Jameson, Director of the Department of Historical Research in the Carnegie Institute of Washington, November 30, 1927. The full memorandum can be found in *John Franklin Jameson and the Development of Humanistic Scholarship in America*, pp. 257–270.

The old-fashioned elegance of Jameson's question notwithstanding, the sentiment lies beneath the mission of the NHPRC's ongoing work as the grantmaking affiliate of the National Archives and Records Administration.

The National Archives and the National Historical Publications Commission (NHPC) were born on the same day in 1934 after about 50 years of gestation. The idea, put simply, was for the Archives to be the steward of the national record and the Commission to select, publish, and tell the story of eminent and important figures from that national record and, importantly, from the archives and records not under the control of the Federal Government, including local and state government, colleges and universities, other nongovernmental organizations, and individuals. Implicit in the idea of the Commission is that the papers of Thomas Jefferson, to take one example, are part of America's documentary heritage, belonging to all of the people, no matter who owned the particular original documents.

The Commission itself met sporadically during the Great Depression, through the war years, and afterward. In 1950, however, a chance encounter took place in The White House that proved catalytic. Impressed by Volume 1 of *The Papers of Thomas Jefferson* presented to him by Julian Boyd and the Princeton University Press, President Harry Truman proposed a comprehensive program for the publication of the public and private writings of persons who have contributed greatly to the development of the United States. A spirited debate over the proposal ensued among historians, and the Commission worked through 1952 to expand and refine its scope.

Early in 1954, a final report to President Eisenhower, *A National Program for the Publication of Historical*

Documents, recommended 361 individuals as worthy of consideration for a national publications program, and it singled out 112 persons, including the five Founding Fathers, for immediate attention. Together with the Jefferson papers, these series became the core of the NHPC's editions program. The report also recommended selective editions for 107 individuals, and three series called for the Federal Government, rather than a private publisher, to produce the documentary editions on the Constitution and the First Federal Congress.

An additional report to President Kennedy (*Report to the President containing a proposal by the National Historical Publications Commission to meet existing and anticipated needs over the next ten years under a National Program for the collection, preservation, and publication, or dissemination by other means of the documentary sources of American History*, Washington, D.C.: Government Printing Office, 1963) laid the groundwork for approaching Congress for appropriations, and in 1964, the Commission was funded for a national grants program: the Public Law 88–383, signed by President Lyndon Johnson on July 29, 1964. By November of that year, the NHPC awarded its first grants—a total of \$350,000—for historical documentary editions.

Another decade slipped by, and the National Archives changed into the National Archives and Records Service (as part of the U.S. General Services Administration. NARS became the National Archives and Records Administration when the agency gained independent status in April, 1985) and NHPC became the NHPRC, acknowledging its responsibility for preservation of original records as well as publishing through grants and other assistance. With the increased responsibility for "records," NHPRC's budget shot up to \$2.5 million in Fiscal Year 1975, and the Commission recognized that to effectively carry out its preservation mission, it had to involve the states. The Commission mandated and began working with State Historical Records Advisory Boards for planning and grant review, then for implementation of those plans, actual archival strategies, and operations, and finally for regrants to local archives and records centers within the states. The 1998 reauthorization of the NHPRC made explicit the *raison* for the NHPRC, amending the language of the enabling legislation to include the Commission's training and education programs, and its partnership with the states:

Section 4, Duties and Functions (a) The Commission shall make plans, estimates, and recommendations for historical works and collections of sources it considers appropriate for preserving, publishing or otherwise recording at the public expense. The Chairman of the Commission shall transmit to the President and the Congress from time to time, and at last biennially, the plans, estimates, and recommendations developed and approved by the Commission. (b) The Commission shall cooperate with, assist

and encourage appropriate Federal, State, and local agencies and nongovernmental institutions, societies, and individuals in collecting and preserving and, when it considers desirable, in editing and publishing papers of outstanding citizens of the United States, and other documents as may be important for an understanding and appreciation of the history of the United States. (c) The Commission may conduct institutes, training and educational programs, and recommend candidates for fellowships related to the activities of the Commission and may disseminate information about documentary sources through guides, directories, and other technical publications. (d) The Commission may recommend the expenditure of appropriated or donated funds for the collecting, describing, preserving, compiling and publishing (including microfilming and other forms of reproduction) of documentary sources significant to the history of the United States and for the activities described in subsection (c). (e) The Archivist of the United States may, within the limits of available appropriated and donated funds, make grants to State and local agencies and to nonprofit organizations, institutions, and individuals for those activities in subsection (d) after considering the advice and recommendations of the Commission.

The Impact of NHPRC Grants

NHPRC awards have helped identify, preserve, and make public the original papers and documents of the Founding Fathers—George Washington, John Adams and Family, Thomas Jefferson, Alexander Hamilton, James Madison, and Benjamin Franklin. Other multivolume editions trace the history of the first Congress, the first Supreme Court, and Ratification of the Constitution. And two hundred or so other Americans—rebels and mavericks, explorers and fighters for justice and equal rights, Presidents and pioneers—have had their legacy preserved and published through printed volumes that number in the hundreds, reels of microfilm that stretch into thousands of feet, and new Web sites on the Internet. Among the noteworthy figures are Martin Luther King, Jr., the expeditions of Lewis and Clark, Abraham Lincoln, Thomas Edison, and many more. These papers projects provide easy access to our documentary heritage—but these are not endings in and of themselves.

Rather, the publishing function of NHPRC is only the beginning, and the effect of its grants ripple out to new interpretative works—dozens of biographies, histories, textbooks, and reconsiderations. Drawing on the works of the 27-volume edition of *The Papers of Alexander Hamilton*, historian Ron Chernow recently published a new monumental biography that may restore Hamilton's reputation and place in American history. Virtually every new American history or historical biography has tapped into the rich vein of source materials uncovered through NHPRC-supported projects.

Plays based upon the words of slaves and the newly emancipated have emerged from the primary sources

uncovered through NHPRC support, along with documentary films and television programs—from *The Civil War* to *Emma Goldman*. New curricula have been created at history classes in high schools, colleges, and universities, and new editions of textbooks reflect what educators have learned through close examination of these published primary sources. On the Internet, users can read the original documents of Eleanor Roosevelt, listen to Kennedy White House tapes from the Cuban Missile Crisis, or read a “mini-edition” of the *Papers of Frederick Douglass*. And these new stories have the ripple effect of deepening and broadening people's understanding of their own history and the individual's place in the American story.

To grasp the impact of the program, take the example of the Freedom History Project, a highly selective edition of documents pertaining to black American life in the years between the beginning of the Civil War and the advent of Reconstruction. The Freedom History Project has kept a cumulative tabulation of how people are using its publications. For example, the papers have been cited in 23 reference works, 15 documentary editions, 130 monographs, 212 scholarly articles and essays, and 68 college-level textbooks and anthologies. At least 152 college courses have made use of the work, as well as 41 teacher workshops, 8 publications for elementary and middle school teachers, 3 CD-ROMs, 9 books for young readers, 24 books for popular audiences, 9 exhibits, 6 films, 11 television programs—including Ken Burns's Civil War series, 16 radio programs, 80 stage productions, and 176 Web sites. One of the editors of the project, Steven Hahn, also wrote *A Nation Under Our Feet: Black Political Struggles in the Rural South from Slavery to the Great Migration* (The Belknap Press of Harvard University Press) which received the 2004 Pulitzer Prize for History. Virtually every scholar of American history has benefited, at one time or another, from works preserved and published through the NHPRC. And even all of these related “products” produced out of the primary sources are still means to an end: to give citizens a better understanding of our nation.

Understanding of our democracy, history, and culture, however, is not limited to the study of great men and women, nor is the American story complete without broad access to the documentary heritage of our states and territories, our great cities and towns, and the records held in smaller repositories across the nation. The NHPRC began to fund the underlying archival work of identification and preservation of documents and records in 1974 through grants to local archival institutions. Coupled with the direct grants to state archives and historical repositories for records preservation and access, the accumulative impact has been to strengthen and develop a national archival system.

Grants through this program have helped preserve and make accessible documents and records throughout the country—from the records of the Rhode Island towns'

meetings to ratify the U.S. Constitution to the oral histories of the Crow tribe in Montana. NHPRC helped the Boston Schools Desegregation-Era Records Project find and preserve records in danger of being lost in a flooded basement, and the Cook County (IL) Local Records Commission discover Chicago's original record of the city council's vote for incorporation from September 1833, long thought destroyed by the Great Chicago Fire of 1871. Through finding aids and database construction, individual users are now able to go online and search through photographs of Colorado's railroads at photoswest.org, daguerreotypes from Harvard University, the whaling industry at the Nantucket Historical Society, and the University of Pittsburgh's Archives of Industrial Society. Genealogists are able to drill down into the records of pioneers and early settlers to Utah. Environmentalists can dig through the archives of the Sierra Club at the University of California's Bancroft Library. Researchers and historians can visit scores of historical societies, libraries, universities, archives, and state and local governments, and their chances of finding the evidence they seek have been greatly improved through NHPRC grants. A complete list of grants from 1976 onward can be found on the NARA Web site at http://www.archives.gov/grants/funded_endorsed_projects/states_and_territories/.

Just as the documentary editions and records program grants produce results beyond their own intrinsic worth, the NHPRC also has invested in other ways to strengthen the archival infrastructure. Since 1967, the Commission has awarded fellowships in documentary editing, and for the past 38 years has sponsored a two-week summer seminar for editors known informally as "Camp Edit," most recently at the University of Wisconsin. In 2008, the Commission also established its Archives Leadership Institute, also at the University of Wisconsin, to provide leadership training to the next generation of archivists and records managers.

Through grants to national professional associations, such as the Society of American Archivists, the National Association of Government Archives and Records Administrators, the Association for Documentary Editing, and others new archival tools and techniques have developed—from basic handbooks for archivists to greater dissemination of sophisticated electronic descriptive tools and standards, such as MARC and Encoded Archival Description. In the wake of the devastating hurricanes Katrina and Rita, the NHPRC entered into a groundbreaking partnership with the Council of State Archivists (CoSA) to

provide disaster preparedness training for archives and records centers, and through grant support it helped in the recovery efforts in Alabama, Texas, and Louisiana. Out of this partnership and the longstanding partnership with CoSA, new efforts are underway to establish a Partnership for America's Historical Records that would provide bloc grants to the states, and in 2008, the NHPRC began a new program to allow the states—through their historical records advisory boards—to undertake new programmatic initiatives and to plan for a true national archival network.

The NHPRC was the first Federal agency to fund research and development efforts to preserve electronic records—records either "born" digital or digitized—beginning in the late 1980s and continuing through this day at projects such as the San Diego Supercomputer Center's Distributed Custodial Preservation (DCP) Center for electronic records. The DCP Center will develop a cost model for providing preservation services for electronic records by developing the iRODS (integrate Rule-Oriented Data System, <http://www.irods.org>) to meet the needs of state archives and other repositories. More recent efforts in digitization are helping archives digitize entire collections, helping preserve records ranging from the work of natural conservation pioneer Aldo Leopold to an exploratory effort to bring online the works of the Founding Fathers.

Results of all this Federal funding can be measured by finding aids or cubic feet of records been saved, research requests of visitors through the doors or Web sites of thousands of repositories. In the greater sophistication the archival field brings to its task of preserving and publishing. In the sheer number of hidden collections now exposed and neglected records uncovered in a courtroom basement or warehouse attic. But the data say what data everywhere says. These measures are not the end. The real measure is in the connection made between the National Archives and Records Administration, the national archival system, and the millions of American citizens who use and benefit from the record of our democratic experiment.

The NHPRC is a bridge to and from the National Archives and the thousands of repositories where the essential evidence is channeled and stored. NHPRC provides funding and leadership. It is a signal commitment from the Federal Government to the local historian in Peralta, New Mexico, to the graduate student in Knoxville, Tennessee, to the genealogist in Juneau, Alaska, to readers, searchers, and explorers of our democracy, history, and culture wherever they may be.

National Libraries

Ian McGowan

Former Librarian, National Library of Scotland, Edinburgh, U.K.

Abstract

The entry describes the various attempts that have been made to define the role and functions of national libraries. The historical background is reviewed, beginning with the royal libraries of Europe, and examining the growth in the number of national libraries in nineteenth-century Latin America and in the postcolonial world of the twentieth century, leading to the most recent wave of national library creation following the dissolution of the Soviet Union. The main collaborative organizations of national libraries are described and the prospects for national libraries in the changing circumstances of the digital age are considered.

INTRODUCTION

Any consideration of national libraries should begin with the definition of what a national library is and what it does. Since every national library is distinctive, if not unique, in its historical origins, development, functions and position within a country's library system, it is not surprising that in the past a simple definition has proved elusive. The evolution of these attempts at a definition is traced, from the earliest, mainly under the auspices of UNESCO, to the more recent approaches that tend to focus on roles rather than functions.

A brief historical overview of national libraries and their services is provided, grouping them into the successive waves by which they appeared, from the early royal libraries of Europe to the new national libraries of the post-Soviet world. This is followed by a more detailed look at the complex and varied evolution of a few notable examples. Since the 1960s there has been significant growth in the main cooperative organizations that national libraries have created in order to pursue collaborative projects and these organizations are described, together with the activities that they have made possible.

Finally, the prospects for national libraries in the digital age are considered, including the threats that are posed by the alternative providers of the information previously only accessible in the large collections of national and research libraries, and the opportunities that exist for extending national libraries' reach, for example through Web-based services.

WHAT IS A NATIONAL LIBRARY?

The question of definition is one that has exercised many writers on national libraries. Because these libraries can differ dramatically in size and function, their nature is not

subject to a straightforward, and short, definition. In the well-known comparison suggested by one of the most prolific and respected of thinkers about national libraries, Maurice Line, "national libraries are in fact rather like dogs: dogs also exhibit an enormous variety, but we somehow recognize them all as dogs [. . .] Anything that is said about national libraries (or dogs) is almost certain not to apply to one or another specimen. Just about the only thing they (dogs and national libraries) have in common is that they all have very hearty appetites."^[1]

With the notable exception of the work of Esdaile,^[2] the literature on national libraries before the mid-twentieth century is sparse, authors perhaps assuming that their nature was self-evident. However, stimulated by a series of seminars sponsored by UNESCO in the 1950s and 1960s, the discussion about national libraries, what functions they should have and what role they should play in a country's overall provision of library services, became more intense and systematic. In 1966, K. W. Humphreys summarized the various activities of national libraries and divided them into three categories—essential, desirable, and inessential.^[3] The essential functions included the holding of an outstanding collection of the nation's literature, the receipt of publications by legal deposit, wide coverage of the scholarly literature of other countries, the publication of the national bibliography, operating as the national bibliographical information center, the publication of catalogs, and the creation of exhibitions. The desirable functions were seen as the organization of interlibrary lending, coordination of the nation's manuscript and archive activities, and research on library techniques. Other activities, described as "functions of the national library service which are not necessary functions of the national library" were the international exchange service, the distribution of duplicates, the provision of books for the blind, professional training, and advice and assistance to other libraries on library techniques.

Another approach to the classification of national libraries is exemplified by Burston's analysis by type.^[4] This identifies institutions such as "cultural national libraries"—those libraries providing services to major administrative regions, sometimes formerly independent, of federal states. "Dual-purpose libraries" include "national-academic libraries" and "national-public libraries," which combine their national responsibilities with services aimed at specific groups, as well as "national-parliamentary libraries," such as the Library of Congress in the United States and the National Diet Library of Japan, which not only serve the country's legislature but also operate as de facto national libraries. The growth of national subject libraries was seen as a recognition of the fact that no one library could hope to achieve complete coverage of global publishing output, but this might still be feasible in a particular subject area, especially in scientific and technical fields, for example those covered by the National Library of Medicine and the National Agricultural Library in the United States.

Sylvestre's *Guidelines for National Libraries*,^[5] prepared and published under the auspices of UNESCO's General Information Programme, advanced the definition of a national library by describing the functions "on which there exists a very large measure of agreement." According to these *Guidelines*, the fundamental task of the national library is to acquire, preserve, and make accessible the publications of the country, and legal deposit legislation is seen as the most effective means to make this collection of the nation's literature as comprehensive as possible. The national library should also acquire foreign literature, although Sylvestre recognizes the practical and financial limitations to this aspect of collection building, and suggests that in some instances the national library might be best suited to promoting and monitoring a national acquisitions plan, aimed at the avoidance of duplication of effort by other collecting institutions, rather than seeking to acquire foreign material widely itself. The collection of manuscripts of national significance, other than public records, should also be given high priority. The national library should normally contain a country's national bibliographic agency, responsible for compiling the current and retrospective national bibliographies. The national library's public services should aim to complement, rather than duplicate, those offered by the nation's other libraries, and should be supported by adequate reading rooms, reprographic facilities, current catalogs, professional advice, and permanent and special exhibitions. Sylvestre places more weight than earlier writers about national library functions on the need for programs to ensure the preservation of library collections, including then novel techniques such as digitization, and recognizes the conflict inherent in satisfying the needs of present researchers while safeguarding collections for future generations. The *Guidelines* suggest that national libraries need to seek public support through consultation with their users, and engage in research

related to the improvement of services. They should encourage the development of nationwide library networks, using the best technology currently available, but making sure that their services are accessible to libraries at various levels of technological development. The national library should act as the clearing house for the international exchange of publications and participate in international library programs, regional and worldwide. Sylvestre suggests that national libraries should preferably be separate organizations with a clear mandate to provide nationwide services, but when they are attached to another institution, such as a university, the services to that parent institution should not have a detrimental effect on national services. Whether responsibility for national library services lies with a single institution or is distributed between two or more institutions, the national library should be the lead body for promoting cooperation among the country's libraries.

Line's *National Library and Information Needs*^[6] is described by the author as complementary to Sylvestre's *Guidelines*, in that it considers national libraries from the point of view of national information needs, rather than from national libraries' existing practice. In this analysis, Line identifies the paradox that developed countries are most likely to be able to afford and already have a national library, but their need for a national library is less than that of the developing countries, who may find it more difficult to justify in economic terms. The sequence of documents on national libraries published by UNESCO was continued by Cornish,^[7] who discusses the various functions that a national library might reasonably be expected to exercise and the impact of new information technology on the way a national library should carry out those functions. He acknowledges the difficulty of defining a national library, and concludes that there are only three characteristics that most have in common: they are funded mainly from the public purse, they are open to the public, and they act as the major archive of printed material produced within the country concerned. *Guidelines for Legislation for National Library Services*,^[8] designed to be of particular use to developing countries without a satisfactory legislative basis for the national library, proposes an updated definition that encompasses both the "heritage" and "infrastructure" responsibilities that a modern national library should embrace:

National library: an institution, primarily funded (directly or indirectly) by the state, which is responsible for collecting, bibliographically recording, preserving and making available the documentary heritage (primarily published materials of all types) emanating from or relating to its country; and which furthers the effective and efficient functioning of the country's libraries through the management of nationally significant collections, the provision of infrastructure, the coordination of activities in the country's library and information system, international

liaison, and the exercise of leadership. These responsibilities are formally recognised, usually in law.

Reexamining the position of national libraries in the digital environment of the twenty-first century, Brindley suggests a definition based on roles rather than functions: support for research, preserving the cultural heritage and providing a locus for national cultural identity, support for the knowledge economy, support for education and lifelong learning, support for community development, support for citizens, and leadership for the library system.^[9]

It can be seen from these evolving definitions that many activities can reasonably, but not necessarily, form part of what the national library does. In addition to the commonly encountered tasks of collection building and management, the national library may offer services to a specific target audience, such as the scientific, business, and industrial communities, or develop cultural programs for the wider public—a “Centre for the Book,” musical performance, lectures, exhibitions. It may maintain the agencies assigning International Standard Book Numbers (ISBNs) and International Standard Serial Numbers (ISSNs), promote research and development in areas relevant to library and information services, and manage information and document supply networks.

The legislative position of national libraries exhibits as much variety as the work they perform. Typically they are answerable to a ministry with responsibility either for education or for culture and the arts, although there are many variations to this pattern. A number of national libraries have a direct link to the office of the head of the government, and this arrangement can be of particular benefit to the institution. It is not uncommon for a national library to have a representative, nonexecutive board providing advice and guidance, and in some cases direct managerial control.

HISTORY AND DEVELOPMENT OF NATIONAL LIBRARIES

Europe

The earliest form of national library, that of a library founded on the collections of royal and aristocratic personages, expanding through the acquisition of collections from a variety of sources, taking on the responsibilities of legal deposit and a range of services to a wider public, can be seen in many of the national libraries of Europe. The Austrian National Library, for example, which was established in 1920, can be seen as heir to the library of the Holy Roman Empire and the Hapsburg Imperial Court Library (Fig. 1). Some libraries retain their royal identity, for example Sweden’s Kungliga biblioteket, the Bibliothèque royale de Belgique, Denmark’s Kongelige Bibliotek, and the Koninklijke Bibliotheek of the Netherlands. Others have made their “national” role explicit, for example Spain’s Biblioteca Real, which assumed the title Biblioteca Nacional as early as 1836.

Not all European national libraries have their origin in royal libraries. Learned and patriotic societies are another historical starting point: The National Library of Ireland was founded in 1877 on the basis of the collections of the Royal Dublin Society; The Slovak National Library grew from the national cultural organization Matica slovenská. Hungary’s National Széchényi Library honors in its name the donor of its first collection, Count Ferenc Széchényi (1754–1820), who saw the establishment of a national library as the natural accompaniment to a national academy of sciences, and until 1949 the Library operated within the framework of the National Museum. Other national libraries had affiliations with private organizations and individuals: the National Library of Scotland

Fig. 1 The Austrian National Library, Heldenplatz.
Source: Photograph: Austrian National Library.

was founded, with a substantial private endowment for running costs, on the basis of a gift to the nation of its collections by the Faculty of Advocates, a private legal association. The National Library of Portugal illustrates the link that sometimes existed between early forms of legal deposit and the control and censorship of publications. The Library can date its origin to the creation of the Mesa Censória in 1768, which examined works submitted for publication and received a copy of each work that was approved for publication and printed. Italy has libraries called Biblioteca Nazionale Centrale in both Florence and Rome. The newer institution in Rome, founded in 1876, reflected the desire to furnish the new capital of a united Italy with a symbol of the national culture. National responsibilities continue to be divided between the two libraries, although both collect material of national interest. Florence, for example, houses the national bibliographic agency, while Rome maintains the National Centre for Manuscripts.

In some instances the functions of a university library have been combined with national responsibilities: in the case of the National Library of Finland and the National Library of Norway, for example, it is only in recent years that they have separated organizationally from the universities of Helsinki and Oslo. The National Library of the Czech Republic, housed in the famous complex of buildings known as the Klementinum, was born out of the University Library of Prague, which received a donation of books from the Emperor Charles IV in 1366. In 1769 the library was open to the public and later in the century was named "Public and University Library." In 1935, in the period of the Czechoslovak Republic, it became the National and University Library, and has been known as the National Library since 1990.

In all these cases, however varied, the concept of nationhood is obviously a vital factor in the libraries' creation. The National Library of Bulgaria, for example, is the oldest cultural institution in the country, dating from 1878, shortly after the country gained its independence from the Ottoman Empire. In 1747 the public library which was to be the forerunner of the National Library of Poland was founded in Warsaw by the brothers Józef Załuski, Bishop of Kiev, and Andrzej Załuski, Bishop of Cracow. By the 1780s the library was placed under the control of the Commission for National Education and had received the right of legal deposit. After the partition of Poland in 1795, the library's collections were moved to St. Petersburg. It proved possible to recover some of this material after the Russian Revolution and the end of hostilities between Russia and the independent Polish Republic, but much had been lost and therefore could not be returned to the new National Library of Poland, established in 1928. After the Nazi assault on Poland, many of the National Library's collections were destroyed, either at the time of the invasion or after the Warsaw Uprising of 1944, as part of the attempt to obliterate all manifestations

of Polish culture. Unfortunately such attacks on national cultural identity are not just a matter of history, as the destruction of the National Library in Sarajevo in 1992 sadly demonstrated.

Latin America

The rise of the national library as an explicit statement of national identity is linked, in particular, to the emergence of newly independent states in Latin America at the beginning of the nineteenth century. These new nations naturally wanted to ensure that their history and literature was recorded and retained and also to demonstrate their independent status through the symbols of statehood. In some instances, the new national libraries were created on the basis of existing institutions. The National Library of Colombia, for example, had its origins in the Real Biblioteca Pública del Nuevo Reino de Granada, which opened to the public as early as 1773; the National Library of Ecuador similarly originated in the Biblioteca Pública founded in 1792. The National Library of the Republic of Argentina traces its roots to the creation of the Biblioteca Pública de Buenos Aires after the Revolution of 1810. Others, such as the National Library of Peru, owed their existence to the country's proclamation of its independence—its governor, José de San Martín, issuing the ordinance establishing the national library only a matter of weeks after proclaiming Peru independent in 1821, and also donating his own collection of books to the library. The foundation of the National Library of Chile in 1813 made it one of the first state institutions created after Chile's declaration of independence in 1810, although its core collection was the existing colonial library of the Jesuits. The National Library of Brazil, inaugurated in 1810, the same year as the Biblioteca Pública de Buenos Aires, is unusual in that it owes its foundation collections to events many miles away in Europe. One of the casualties of the Lisbon earthquake of 1755 was the royal library, and following its destruction a new royal library was assembled which included the collections of the bibliographer Diogo Barbosa Machado and books from the Portuguese Jesuit colleges. When the forces of Napoleon entered Portugal, the royal family and the royal library departed for the then colony of Brazil. When João VI returned to Portugal in 1821, the royal library remained, becoming public property after the proclamation of Brazil's independence in 1822. It was not uncommon for the national libraries of Latin America to be associated closely with a university. The National Library of Chile was linked to the Universidad de Chile until 1852; the National Library of Colombia was attached to the National University after 1867. In North America, the National Library of Mexico also has long-standing associations with the National Autonomous University of Mexico. Although the first attempts to establish a national library of Mexico date to the 1830s, it was not until 1856 that a

decree of the President proposed the establishment of the National Library, which came into existence the following year after the suppression of the University of Mexico and the assigning of its building and books to the National Library. The National Library was not immune from the political upheavals experienced by Mexico in the nineteenth and early twentieth centuries, but with the granting of autonomy to the University of Mexico in 1929, control of the National Library passed from a department of government to the University itself, and is now under the administration of the Institute of Bibliographic Investigation. The National Library still forms part of the cultural complex on the university campus, Ciudad Universitaria.

National Libraries in the Postcolonial World

The former British Dominions (self-governing territories of the British Commonwealth) tended to have developed library systems at a relatively early stage in their political and economic development. The National Library of New Zealand (in Māori Te Puna Mātauranga o Aotearoa) was formed by the merger of three institutions: the General Assembly Library created in 1858 to serve Members of Parliament; the Alexander Turnbull Library, a research collection bequeathed to the nation and opened to the public in 1918; and the National Library Service, which brought the Country Library Service and the School Library Service together in 1945. The updated legislation of the National Library of New Zealand Act 2003 placed more emphasis on the responsibilities of the Library toward Māori heritage and knowledge, and extended legal deposit to electronic publications.

Library and Archives Canada/Bibliothèque et Archives Canada (LAC) was created in 2004 with the merger of the National Library of Canada (dating from 1953) and the National Archives of Canada (dating from 1872), thereby establishing one of the few organizations in the world to bring together an existing national library and national archives. The intention was not simply to bring two sets of functions under a single administration, but to create a fully integrated knowledge-based institution. The legislation establishing Library and Archives Canada introduced the term “documentary heritage” to encompass all recorded information about the country, including electronic media, which are now subject to legal deposit. Library and Archives Canada also harvests a representative sample of Canadian Internet sites for preservation purposes.

Before the creation of the National Library of Canada, national library functions fell to the Library of Parliament. Similarly, Australia's Commonwealth Parliamentary Library, inaugurated in 1902 after the model of the Library of Congress, enjoyed the legal deposit privilege from 1912 and formed the basis of the National Library of Australia. The National Library Act 1960 separated the National Library from the Parliamentary Library and a new building

for the Library was opened in Canberra in 1968. The Library has been at the forefront in exploring the preservation of digital information, and is committed to the exploitation of its collections through digital technologies.

In the twentieth century a further wave of national libraries accompanied the emergence of new nations in the postcolonial period. This was seen clearly in Africa, although the term “bibliothèque nationale” was used more frequently in francophone Africa than “national library” in Anglophone countries, where a national library service was often introduced. In Ghana, for example, which gained its independence from Britain in 1957, the Ghana Library Board was established to set up and manage public libraries. However, it is also responsible for the George Padmore Research Library, which acts as a National Library in the absence of a statutory body. The Kenya National Library Service was established by an Act of Parliament in 1965 in order to develop public library services, but it too carries out a range of services within the remit of a national library, such as acquiring comprehensively material published in Kenya and abroad about the country, providing bibliographic and reference services, and publishing the national bibliography. A similar picture is seen in Botswana, where a Division of the Botswana National Library Services administers the acquisition of books by legal deposit and produces the *National Bibliography of Botswana*. Zambia also lacks specific legislation for a national library service, but the Zambia Library Services, a unit in the Ministry of Education, undertakes a range of national functions. The National Library of Nigeria was established by the National Library Act 1964, which was unusual among national library legislation in that it called for the creation of a branch of the National Library in each of the country's States. As a result of the political situation in the country, as well as the familiar financial pressures, the Library still has some way to go in achieving the goal, although branches now exist in some 14 States. Uganda has taken the step of repealing its Public Libraries Act 1964, which established a Public Libraries Board responsible for managing libraries nationally in Uganda, and replacing it with the National Library Act 2003. Responsibility for libraries had already been decentralized in 1997 by new local government legislation, and the 2003 Act established the National Library of Uganda as an advisory body for national library policy and the executive body for managing legal deposit, maintaining the national collection, and publishing the national bibliography. The national libraries of Africa face the most challenging conditions of any national libraries. The economic and political environment in which they operate, and the competing needs of other pressing social and economic concerns, can make the role of the national library seem marginal. Nevertheless, in many countries the impact they make in support of national library services and the importance they have as national symbols are clearly significant.

The most developed national library of sub-Saharan Africa is undoubtedly the National Library of South Africa. Until its creation in 1999, South Africa had two libraries performing national library functions, the South African Library in Cape Town, founded in 1818, and the State Library in Pretoria, founded in 1887. For historical reasons both libraries received South African publications by legal deposit legislation which dated back to the middle of the nineteenth century. The South African Library, formerly the South African Public Library, developed as a national reference library, whereas the State Library operated as both a public and a national library, being a center for national functions such as exchange agreements, bibliographical information, and interlibrary lending. The new National Library, created from the reconstitution of these two libraries as a single entity on two sites, was seen as reflecting the goals of democratic, postapartheid South Africa.

The national libraries of North Africa are distinguished by rich historical collections, particularly of manuscripts, their national status tending to center on the preeminence of their collections rather than their role in a system of national information provision. The National Library and Archives of Egypt, founded in 1870, and the National Library of Tunisia, founded in 1885, for example, both contain collections predating the creation of these libraries by many centuries. Both are now embracing the possibilities provided by new technology to digitize and make available their collections internationally. In Morocco, the *Bibliothèque Générale et Archives*, established in 1926, undertakes the functions of a national library through the legal deposit privilege and the publication of current and retrospective bibliographies, as well as the collection of manuscripts and the production of catalogs of manuscripts. The National Library of Algeria traces its history to 1835 but considers its new library building, fully opened in 1998, essential for its mission of providing access to information for a wide public, including children and young people, who are seldom catered for specifically by national libraries.

The distinction between a national library and a national library service, which is a recurring theme in any account of national libraries, is illustrated by the different development paths taken in Jamaica and in Trinidad and Tobago. The National Library and Information System of Trinidad and Tobago (NALIS) was created by legislation in 1998. This legislation formalized the integration of three public library systems, the Trinidad Public Library, founded as a subscription library in 1851; the Carnegie Library, opened in 1919; and the Central Library of Trinidad and Tobago, established in 1941. The result was a structure that provided traditional public library functions through its administration of a network of branch and mobile libraries, as well as school and special libraries, while meeting the heritage obligations of a national library, including the maintenance of a legal deposit

collection and the creation of the national bibliography. On the other hand, the National Library of Jamaica began its operations in 1979 against a backdrop of an existing public library system and its role in coordinating the national information system depends on its ability to manage various cooperative relationships among autonomous bodies.

The national libraries of Asia generally were founded relatively recently, although they may have much earlier historic roots. The National Library of Thailand, for example, like many European national libraries, was founded on the basis of a number of royal libraries, brought together in 1905. As well as the buildings within the National Library complex in Bangkok, there are now 17 provincial branches of the National Library throughout Thailand. The Library not only has the oldest and largest collection of manuscripts and printed books in the country, but also provides a range of services, such as training courses and document delivery, to other libraries. It is the National Bibliographic Agency of the country, assigning ISBNs and ISSNs and publishing the national bibliography. The forerunner of the National Library of China, the Metropolitan Library, was also created at the beginning of the twentieth century (1909) at a time of expanding Western influence and operated as a legal deposit library from 1916. From 1928 the Library was known as the National Peiping Library, and after the founding of the People's Republic of China as the Beijing Library. Its *de facto* national status was recognized when it was renamed the National Library of China in 1998. It contains the largest collection of Chinese books in the world and the largest collection of foreign books in China. It serves the country's library system by acting as a center for library research and development, as the national bibliographical center, and the center for national information networks. These national functions extend to the responsibilities the Library has for three important national cultural projects: the National Cultural Information Resources Sharing Project, the Chinese Rare Book Facsimile Project, and the Rural Area Book Distribution Project. The implementation of the National Digital Library of China Project and the National Library of China Phase II approved in 2001 illustrates the way that the rapid growth of China as an economic power is permitting substantial investment in the country's information infrastructure.

The emergence of many of the national libraries of the region can be seen as part of the process of national building in the postcolonial period. The National Library of Malaysia began as a unit in the National Archives of Malaysia in 1966, before becoming a separate federal department under the National Library Act 1972. A high priority for the Library is the collection of materials published in and about Malaysia and the Library's Centre for Malay Manuscripts contains the world's largest single institutional collection of Malay manuscripts. The Library's building is itself an unusual physical expression of

national identity, since its design was inspired by the traditional Malay headdress, reflected in the shape of the building's roof and symbolizing Malaysia's achievement and culture. The National Library of Indonesia was established in 1980 as the result of the amalgamation of four existing libraries. In 1989, a further merger with the Centre for Library Development extended the Library's responsibilities. As well as undertaking the common national library functions such as building the national collection and providing bibliographical and reference services, the Library develops national policies in the library sphere. Through the Provincial National Library, a division of the National Library of Indonesia, it maintains a presence throughout the country. In Sri Lanka, the National Library developed to encompass documentation services when in 1990 it became the National Library and Documentation Centre with a clear mandate to provide information resources to the whole population. Its central role has been demonstrated in recent years through the leadership it has brought to the reconstruction of libraries following the devastation caused by the tsunami of December 2004. The National Library of Singapore was established in 1958, although its origins can be traced to the Singapore Institution founded in the 1820s. Since 1995 it has been under the administration of the National Library Board and integrated into a national system including regional, community, and children's libraries, with all publicly funded libraries in the country linked to the totality of the country's information resources. In Singapore the role of libraries has been recognized as crucial for the successful development of a knowledge-based economy, and the *Library 2010 Report* defines its current objective as "to bring the world's knowledge to Singapore to create a positive social and economic impact."

The origins of the National Library of India date to 1836 and the creation of the Calcutta Public Library, a subscription library that from its earliest days made provision for limited use free of charge by indigent scholars and others who were unable to afford the subscription. At the end of the nineteenth century an Imperial Library was formed to serve the needs of the Government, and with an amalgamation of this library with the Calcutta Public Library in 1903, a new Imperial Library, functioning as a general reference and public library, was born. It was intended that it should contain all works written about India in all languages as well as standard reference works. After gaining its independence, the Government of India changed the name of the Library to the National Library of India.

Of the national libraries with a role to serve the legislature, the National Diet Library, Japan, resembles most closely the Library of Congress in its responsibilities. This is not coincidental, as there was significant input to the discussion about the shape of national library services in Japan after the Second World War on the part of an advisory mission of representatives from the Library of

Congress and the American Library Association. New legislation governing the National Diet Library came into effect in 1948. The National Diet Library merged with the old Imperial Library (founded in 1872 and renamed the "National Library" in 1947) to form a single national library providing services to the Diet of Japan and to the general public.

The Post-Soviet World

Following the collapse of the Soviet Union and the subsequent political changes in Central and Eastern Europe, many of the national libraries of the region received a new lease of life. The national libraries of the Soviet Republics began to operate as the cultural representatives of independent states. The redrawing of national borders, in the former Yugoslavia, for example, created sovereign states from previous federations and the national library took its place as a national symbol among other cultural institutions, such as national museums and galleries.

In the case of the Baltic States, their national libraries had been founded after the end of the First World War as the result of an earlier reordering of European nations. The Estonian State Library was founded in 1918, at first primarily for the use of the members of Parliament. It developed as a public library during the Soviet period, but was renamed the National Library of Estonia in 1988. As well as assuming responsibility for building the national collection of works published in and about Estonia, it once more became the library of the national Parliament. The National Libraries of Lithuania and Latvia were established in 1919, both with the title of State Library, emerging from the turbulence of the twentieth century as National Libraries on the restoration of their countries' independence in 1990 and 1991, respectively. The Vernadsky National Library of Ukraine and the National Parliamentary Library of Georgia combine national responsibilities and services to the general public with support for Parliament and government bodies. Some aspects of Soviet library organization survive, as in Armenia, for example, where the National Library of Armenia coexists with the National Book Chamber of Armenia, which remains the center of national bibliographical activity.

In the Russian Federation, the Russian State Library in Moscow (Fig. 2), formerly the Lenin State Library of the USSR, and the National Library of Russia in St. Petersburg, formerly the State Public Saltykov-Shchedrin Library, are the two libraries that both exhibit in one form or another the characteristics of a national library, including the privilege of legal deposit. The Russian State Library has its origins in the collections of printed books and manuscripts bequeathed by Count Nikolai Petrovich Rumiantsev to the nation on his death in 1826. In 1861 the collections were transferred from St. Petersburg to Moscow and, supplemented by other private collections and

Fig. 2 The Russian State Library, Moscow.

selected art works from the Hermitage, opened to the public as the Moscow Public and Rumiantsev Museum in 1862, in effect the city's first publicly accessible library. After the Revolution of 1917 there was a period of substantial growth as numerous private and institutional collections entered the Museum. In 1925 the museum objects were dispersed to other institutions, including Moscow's Museum of Fine Arts (now known as the Pushkin Museum), and the library collections were retained in what was renamed the Lenin State Library. In the Soviet period the Library grew to be the largest in the country, extending into a new complex of buildings constructed in the 1950s, and it remains one of the largest in the world. After the breakup of the Soviet Union, the remit of the Library was adjusted accordingly, no longer being responsible for coordinating the work of the libraries of what had been the Union Republics, and it received the designation of Russian State Library in 1992. The closer coordination of its activities with those of the National Library of Russia dates from this time.

The National Library of Russia was founded as the Imperial Public Library in St. Petersburg by Catherine the Great in 1795 on the basis of the Załuski collection, removed from Warsaw. It was intended to supplement this collection with others already in government hands, including the libraries of Voltaire and Diderot, although in practice it was many decades before these collections were transferred to the Library. The Library's main purpose would be to maintain a complete collection of books in Russian, wherever published, and books about Russia in all languages. The planned opening of the Library's building on Nevsky Prospect in the center of St. Petersburg was delayed by Napoleon's invasion of Russia in 1812 when the most valuable collections were removed from the city for safekeeping, and the Library was finally opened to the public in 1814. Through the efforts of a series of energetic

directors, including Modest Andreevich Korf, whose influence has been likened to that of Panizzi at the British Museum, the Library grew through the nineteenth century to become one of the most notable in Europe. After the Revolution, the Library was known as the Public Library of Russia and, like its counterpart in Moscow, absorbed many library collections from individuals, public bodies, and religious foundations. In 1932 it was renamed in honor of the famous Russian satirist Mikhail Evgrafovich Saltykov-Shchedrin (1826–1889). In 1941 the Library's most precious items were again evacuated when the invading Nazis threatened the city. With great difficulty the Library remained open during the Siege of Leningrad (1941–1944) when the remaining collections were distributed on the lower floors and in underground shelters. The Library's pressing problems of accommodation, felt throughout the twentieth century, were finally addressed with the construction of a new building in the 1990s. Its designation as the National Library of Russia in 1992 confirmed the national functions that it had undertaken to a greater or lesser extent throughout its history, but allowed it a greater independence of action in carrying them out than it had experienced before.

Some Notable National Libraries

While it is impossible in the space available to consider the historical development and individual characteristics of each of the national libraries of the world, a closer consideration of a small number of notable examples can give an indication of their range and complexity.

Bibliothèque nationale de France

The Bibliothèque nationale de France (Fig. 3) is generally regarded as having the strongest claim to being the first

Fig. 3 Bibliothèque nationale de France.

national library. Tracing its foundation to 1368 as the royal library of Charles V, it was the first to receive the country's publications through a system of legal deposit, introduced in France by the Ordonnance de Montpellier of Francis I in 1537. This decreed that a copy of every book printed in France should be deposited in the royal library at Blois and that every book printed abroad and sold in France should be offered to the library for purchase. The library was also the first to be styled "national" when the title of the royal library was changed in 1789 at the time of the French Revolution. By the first quarter of the eighteenth century, as a result of its continual growth, the library reached the point when it needed to be reorganized in some systematic way in order to be managed efficiently and so five separate departments, including Printed Books, Manuscripts, and Prints, were established. From the 1720s, under the king's long-serving librarian, Abbé Jérôme Bignon, the library also became more accessible to the generality of scholars. After the Revolution the library was greatly enhanced by collections confiscated from suppressed monasteries and French émigrés who had not been successful in removing them from the country. The private libraries of Louis XVI and Marie-Antoinette were among the many that entered the national collections at this time, as the library rapidly doubled in size, helped by the spoils of Napoleon's armies. At this time the library occupied part of a complex of buildings adapted from other uses on and around the rue de Richelieu in Paris. In 1856 more of the complex was given over to the library and the government architect Henri Labrousse combined a restoration of existing buildings with newly built book stacks and the famous *salle de travail* which opened in 1868. In the twentieth century, responding to the pressure, familiar to all national libraries, for more space for continually expanding collections, the library had to find various ingenious solutions for extending accommodation on the rue de Richelieu

site, which allowed no horizontal development and was subject to strict controls over any change in its appearance. This increased storage capacity in central Paris was supplemented by three annexes at Versailles built between 1934 and 1971. A radical new phase in the history of the library was heralded by the announcement by the President of the Republic on July 14, 1988 of the construction of a new library which would provide not only conventional storage (albeit in a controversial series of book-shaped glass towers) but would also exploit the most up-to-date technological solutions for the management of information. The new building opened to the public in December 1996.

The British Library

The history of the British Library illustrates some of the complexities that accompany the development of national libraries and the way in which they often reflect the constitutional arrangements of the states they serve. The British Library is the national library of the United Kingdom, but since the United Kingdom is a federal state of four countries, two of which (Scotland and Wales) have their own national libraries, the British Library has a particular responsibility also to act as the national library of England. The British Library is a relatively new institution, established by The British Library Act of 1972, but brought together individual institutions with a much longer history: the British Museum Library, the National Reference Library of Science and Invention (the Patent Office Library), the National Central Library, and the National Lending Library for Science and Technology (Boston Spa). Further additions were the British National Bibliography and the Office for Scientific and Technical Information in 1974, the India Office Library in 1982 and

the British Institute of Recorded Sound in 1983. The library departments of the British Museum date to the foundation of the Museum itself in 1753. The wealthy physician and collector Sir Hans Sloane directed in his will that his collections of printed books and manuscripts, as well as his collections of botanical, zoological, and mineralogical specimens, should be offered to the nation for £20,000. Thanks to a lottery, this sum was raised, together with sufficient funds to acquire the Harleian Manuscripts collected by Robert and Edward Harley, Earls of Oxford, as well as to provide a home for the collections and an endowment for their upkeep. These collections, which formed the basis of the Museum, were enhanced by the acquisition of others, such as the Old Royal Library, presented by George II in 1757, and by the legal deposit privilege. In 1823, shortly after the death of George III, the Museum was presented with the remarkable "King's Library," with the proviso that it should be retained as a separate entity. The King's Library doubled the size of the Museum's collections of printed books at a stroke, and a special gallery was created for it in the new Museum building designed in the Greek style by Sir Robert Smirke. When the British Library's new St. Pancras building was opened in 1998, the King's Library was housed in a striking six-story glass tower, visible to those entering the building and a vivid reminder of the continuity of collecting from the eighteenth century to the present day.

Before the construction of the St. Pancras building, for many users the British Library meant the round Reading Room, built within the quadrangle of Smirke's Museum building in the 1850s to a concept by Antonio Panizzi, the Museum's inspirational and energetic Principal Librarian. However, the institutions brought together by the British Library Act provided a wealth of other services, not only to individual researchers, but also to the scientific community, commerce, and industry as well as to other libraries worldwide. Many users of the Library's services would be unaware that their information requirements, presented to their local library service, would be satisfied with the help of the British Library. The National Central Library and National Lending Library for Science and Technology merged in 1973 to form the British Library Lending Division, later the Document Supply Centre, coordinating and providing loans and supplying documents internationally. The British National Bibliography, unlike the other constituent parts of the British Library, had operated as a commercial company, publishing weekly listings of all British publications, and in its new home in the British Library became a leader in the production of machine-readable catalog records and their exploitation in computerized library management systems.

Die Deutsche Nationalbibliothek

The history of the German national library reflects the political turmoil of the twentieth century. As a relatively

new unified European state, Germany inherited a rich legacy of State libraries, such as the Preussische Staatsbibliothek in Berlin, and the Bayerische Staatsbibliothek in Munich, but no national library as such. The national library was established as the Deutsche Bibliothek after the reunification of Germany in 1990 through a merger of the Deutsche Bücherei Leipzig and the Deutsche Bibliothek Frankfurt. The Deutsche Bücherei was established in 1912 on the initiative of the book trade, the city of Leipzig, center of publishing in the German Reich, and the Kingdom of Saxony. Its remit was to collect, catalog, and make available free of charge German and foreign-language literature published in Germany and German-language literature published abroad. At the end of the Second World War and the division of Germany into four zones by the occupying Allies, a second depository library, the Deutsche Bibliothek, was set up in Frankfurt am Main in the American zone. With the later emergence of two German states, these two libraries became the national libraries of the German Democratic Republic (Leipzig) and the Federal Republic of Germany (Frankfurt). As the two states became one, the two libraries integrated their activities as the Deutsche Bibliothek, which changed its name in 2006 to the Deutsche Nationalbibliothek.

The Library of Congress

The foremost representative of those national libraries whose primary purpose is to serve the legislature of the country, the Library of Congress was established in 1800 by the Congress of the United States when Congress itself transferred from Philadelphia to Washington, D.C., the new capital city. By moving, Congress lost its access to the existing libraries of New York and Philadelphia and \$5000 was appropriated to establish a reference library for Congress, consisting mainly of immediately relevant works, for example on public law and legislative procedures. By 1814 the library had grown to some 3000 volumes when it was completely destroyed by British troops who set fire to the Capitol Building during the War of 1812. Former President Thomas Jefferson immediately offered his personal library, to be purchased on Congress's own terms, as a replacement. The offer aroused some controversy as the library contained literary, scientific, and philosophical works as well as legal and political material, but the purchase was authorized and the collection of over 6000 works was duly bought in January 1815 for \$23,950. The present Library of Congress still maintains the comprehensive collecting policies that have their origin in Jefferson's belief that all subjects are potentially important to a nation's legislators. In 1816 restrictions on the use of the library were eased, so that in practice access was allowed to scholars in general, but it remained in scale and nature a library for Congress, "national in no sense but ownership."^[10] The tenure of Librarian Ainsworth Rand Spofford, which extended from 1864 to 1897, saw the

library strengthened by improved copyright legislation that required deposit at the Library of Congress as a condition for copyright protection for a wide range of printed material, including music, maps, and photographs. To accommodate the growing collections, in 1886 Congress authorized a new library building, now known as the Jefferson Building, completed in 1897, which made a statement about the wealth, prestige, and values of the nation as well as housing the collections in the then most technologically advanced library building in the world. The collections were seen as a resource for the nation and during Spofford's term as Librarian, the library's opening hours were extended to every weekday and eventually to evenings as well.

Even longer serving than Spofford, Herbert Putnam oversaw in his 40 years in the office of Librarian (1899–1939) a tenfold increase in the size of the collections, staff, and funding. A notable achievement was the creation of a centralized cataloging service, supplying printed catalog cards to the country's libraries, supported by other central services such as the national union catalog and interlibrary loans. Putnam also looked overseas to collect material from other countries, for example the Yudin library of Russian literature and important collections of oriental books, and no fewer than three copies of the Gutenberg Bible were acquired with the Vollbehr collection in 1930. The expansion of collections, staff, accommodation, and services continued through the twentieth century, making the library a world resource for scholarship and research, as well as continuing its role of information provision for Congress. Although the library rejected the suggestion that its name should be changed to National Library, and was careful not to claim any directing role over the rest of the nation's libraries, its leadership in many areas of library and information services could not be doubted. Its policy of large-scale acquisition of foreign publication meant that it was the most successful of the national libraries of the world in maintaining the concept of a comprehensive collection. Its pioneering developments in library automation and the digitization of collections to make them accessible remotely have been emulated by many other national libraries wishing to adapt their traditional role of collecting institutions to the changing circumstances of digital technology and the world of the Internet.

NATIONAL LIBRARY ORGANIZATIONS

The Conference of Directors of National Libraries (CDNL) is described as “an independent association of chief executives of national libraries, established to facilitate discussion and promote understanding and cooperation on matters of common interest to national libraries worldwide.”^[11] The Conference was established in 1974 and meets annually, providing an important framework for

international collaboration. Being open to all the national libraries of the world (the list of national libraries on the Web site of the International Federation of Library Associations now contains over 160 entries^[12]), there are practical difficulties in members attending each meeting and partly for this reason a number of regional organizations has been established focusing on national libraries: La Asociación de Bibliotecas Nacionales de Iberoamérica (ABINIA), the Conference of Directors of National Libraries of Asia and Oceania (CDNLAO), the Standing Conference of National and University Libraries of Eastern, Central and Southern Africa (SCANUL-ECS), and the Conference of European National Librarians (CENL).

La Asociación de Bibliotecas Nacionales de Iberoamérica's aims are to encourage the exchange of knowledge and experience among the national libraries of Latin America, for example through collaborative training and the promotion of new information technologies and conservation techniques. Joint initiatives include digitization projects, of the nineteenth-century Latin American press for example, and the creation of a union catalog of Ibero-American musical records.^[13] La Asociación de Bibliotecas Nacionales de Iberoamérica has a special concern to promote the adoption of appropriate and adequate legislation for national libraries.

The 26 members of CDNLAO similarly promote cooperation and the exchange of information.^[14] The CDNLAO Newsletter^[15] records the activities of the Conference and publishes reports and research from the national libraries of the region. The Libraries of Asia and the Pacific Directory,^[16] an initiative of CDNLAO, supported by the National Library of Australia, aims to provide a single access point for retrieval of information about the functions, services, and collections of libraries in Asia and the Pacific region.

The SCANUL-ECS was founded in 1994 with the following aims: to support and develop national and university library services in the areas covered by Eastern, Central, and Southern Africa; to promote interchange, contact, and cooperation among national and university libraries in the region; to collect, coordinate, and disseminate information on library activities; to encourage increased contact among members and the international library community; to organize and encourage conferences, seminars, workshops, and subject meetings; to initiate and implement regional projects and resource sharing; and to promote the participation of the information sector in the major socioeconomic activities in the region.^[17] In support of these aims SCANUL-ECS organizes meetings, supports case studies, and publishes a newsletter.

The CENL, founded in 1987, states its aim to be “increasing and reinforcing the role of national libraries in Europe, in particular in respect of their responsibilities for maintaining the national cultural heritage and ensuring the accessibility of knowledge in that field,” and explicitly elaborates the rationale for a collaborative

approach: “National libraries need to secure their own position in order to establish the conditions necessary for free and unhindered access to information and documentation. This information must be, as far as possible, complete, clearly organised, prompt, and reliable. More than ever before, it is therefore necessary to develop new models of cooperation, to divide work tasks and share resources. National libraries can act as a focus within a cooperative network.”^[18] Conference of European National Librarians draws its membership from the national librarians of the member states of the Council of Europe and acts through annual meetings as well as through specific projects and initiatives. Its mission^[19] is to support the European national libraries in their role to

- Give everybody fast, comprehensive, multilingual, and long-term access to their collections and information, and wherever appropriate without cost.
- Build the European Digital Library.
- Safeguard European national cultural heritage and knowledge.
- Do research and development to improve user services of national libraries.
- Promote cultural diversity and multilinguality as basic values of the European culture.
- Cooperate with other cultural heritage institutions, universities, publishers, and information providers on a European as well as on a global level.

The Conference expanded from the original 11 national librarians from Western Europe with the growth of links to the national libraries of Eastern Europe through the 1990s. The Conference’s priority areas for activity have remained as defined at the first meeting: harmonization and innovation of national policy concerning libraries; implementation of new information technology in the libraries; standardization of data structure and communication interfaces within a European network; and preservation and conservation of important collections in Europe. The Conference working groups illustrate the concerns that are at the forefront of thinking on national libraries in Europe. For example, the challenge to the concept of legal deposit posed by electronic publishing prompted the creation of a “Statement on the development and establishment of voluntary deposit schemes for electronic publications,”^[20] which reflects the level of cooperation currently enjoyed by national libraries and publishers and draws on the need to share the experience of those countries which already have legislation for electronic deposit or developed voluntary deposit schemes.

The European Library (TEL), the Web service of CENL,^[21] gives access to the resources of 48 national libraries in Europe in 20 languages. These resources are both bibliographic, such as catalogs and collection descriptions, and digital (including some 300 photographs of Europe’s national libraries). The European Library states

that it exists to open up the universe of knowledge, information, and cultures of all Europe’s national libraries, and aims to provide equal access to promote worldwide understanding of the richness and diversity of European learning and culture. Starting in 2006, the European Digital Library project, funded by the European Union and managed by CENL, built on TEL with the aim of integrating the digital content of the main European national libraries into a single multilingual service, Europeana,^[22] launched in prototype at the end of 2008. Europeana encompasses not only libraries, but also museums, archives, and audiovisual collections, and is managed by a team based at the national library of the Netherlands, Koninklijke Bibliotheek. The management team is tasked with recommending a business model that will ensure Europeana’s long-term sustainability as a cross-domain portal that will bring together existing digital content and provide support for further digitization of Europe’s cultural and scientific heritage.

Conference of Directors of National Libraries coordinates its activity with the other main forum for the national libraries of the world, IFLA’s National Libraries Section.^[23] The Section’s *Strategic Plan 2007–2009*^[24] lists its goals as

- To promote the universal availability of information by such activities as encouraging the creation and building of national libraries, the development of national legislation for national libraries—especially legal deposit dispositions and preservation activities—and to promote the convergence of information and heritage institutions.
- To serve as a forum to share and learn from the experience of the practical problems of national libraries, in order to promote benchmarking, best practices, and quality models, and to improve management skills.
- To promote research in fields of interest to national libraries, always considering the opportunities to share experiences with other groups within IFLA and in close cooperation with CDNL, and to promote the development and implementation of standards.

As well as producing its regular *Newsletter*,^[25] the Section organizes sessions and workshops at the annual World Library and Information Congress, collaborates with other Sections of IFLA on the Congress program, and contributes to specific projects in support of its strategic plan.

FUTURE TRENDS: NATIONAL LIBRARIES IN THE INTERNET AGE

In 1998, Line posed the question “What do national libraries do in the age of the Internet?”^[26] One new activity is to attempt to manage the information that the Internet has given birth to. While most national libraries still strive to acquire the nation’s printed output (and some also cover

Fig. 4 Kongelige Bibliotek, Copenhagen.

various types of nonprint media), usually by a form of legal deposit, the scope and nature of electronic and Web-based publishing presents particular challenges. As legislation changes to bring electronic publications within the scope of legal deposit, for example in Denmark,^[27] Norway, and the United Kingdom,^[28] national libraries are faced with a series of new responsibilities. The global nature of the Internet can obscure or confuse the national origin of a digital publication. Once the material is identified, systematic methods of harvesting, sometimes volatile and ephemeral, information must be implemented. Information may be subject to legal or voluntary deposit, but contains embedded links that refer to material that is beyond the scope of these arrangements. Other digital publications may contain technological systems to limit or prevent access or copying and rely on changing hardware and software platforms. National libraries now have to devise structures to manage digital information and build digital repositories that address these issues of acquisition, access, and preservation. With the dramatic increase in the resources available via Internet search engines and as a result of commercially funded mass digitization projects, national libraries are looking beyond their former roles and services to find new ways to exploit their collections, whether they be in digital or traditional forms. As well as developing their own individual Web-based services, they are forging new partnerships and working collaboratively, nationally and internationally, to create gateways such as Libraries Australia^[29] and TEL, or supranational digital libraries such as the projected European Digital Library and the prototype World Digital Library.^[30]

Such initiatives might suggest that the day of the national library as a physical expression of national identity and prestige is now gone. However, with major new national library buildings recently completed or planned in countries as dissimilar and widespread as Denmark

(Fig. 4), Belarus, Peru, Latvia, the United Kingdom, the Czech Republic, France, and Korea (where a major new building is to house the National Digital Library), the evidence is that many nations continue to value the symbolic presence of the national library as the visible expression of their history and culture.

National Library of Medicine

Kathel Dunn

National Library of Medicine, Bethesda, Maryland, U.S.A.

Abstract

The National Library of Medicine (NLM) is one of 27 Institutes and Centers of the National Institutes of Health (NIH), located just outside Washington, DC in Bethesda, Maryland, United States. The NLM is responsible to the Department of Health and Human Services (HHS) and to the Congress, which annually reviews its programs and appropriates funds for its operation. The institution was and continues to be a leader in applying computer technology to the handling of large databanks of medical information. This entry provides an introduction to the National Library of Medicine by first discussing some of the library's history and then shifting focus to organizational structure, administration, extramural programs as well as various other aspects of the library.

INTRODUCTION

The National Library of Medicine (NLM) is one of 27 Institutes and Centers of the National Institutes of Health (NIH), located just outside Washington, DC in Bethesda, Maryland, United States. The NLM is responsible to the Department of Health and Human Services (HHS) and to the Congress, which annually reviews its programs and appropriates funds for its operation. The institution was and continues to be a leader in applying computer technology to the handling of large databanks of medical information. Today, it is the largest library of the health sciences in the world. Extensive information about the programs described here is on the NLM's website at www.nlm.nih.gov.

The National Library of Medicine is independent of the other national libraries but works closely with the Library of Congress and the National Agricultural Library in a number of areas to ensure, for example, that acquisitions policies are complementary and cataloging practices are consistent.

Most of the library's programs are housed in three buildings at the southeast corner of the National Institutes of Health campus. Two library divisions, Extramural Programs and Specialized Information Services, as well as some of the staff from Library Operations and the Office of Computer and Communication Systems (OCCS) are housed in leased facilities a couple of miles away. The NLM building, occupied in 1962, contains the collections, technical processing, public services, and administrative offices on five floors (three below ground). The remaining programs are housed in the adjacent Lister Hill National Center for Biomedical Communications Building, a 10-story structure dedicated in 1980, and in the Natcher Conference Center, across the street and north of the other NLM buildings. The permanent full-time staffing level of the library in 2012 was

about 800. The appropriation for the year ending September 30, 2012 was \$337 million.

HISTORY OF THE LIBRARY

The National Library of Medicine had its origin with a collection of books in the office of the U.S. Army Surgeon General, established in 1818. The first request for funds for the library—\$50 for medical books—appeared in the 1836 estimate of expenses for the Surgeon General's Office, and, in 1840, the office issued its first "catalogue of books in the library." The year 1865, when John Shaw Billings assumed charge of the collection, marked a turning point in the development of the library. By 1880 the collection contained 50,000 books and 60,000 pamphlets. Within that decade, books and journals were regularly going out on loan to physicians, and thousands of reference inquiries were being answered annually.

Just as important as the increase in the collection was the publication of reference and bibliographical works inaugurated by Billings. In 1879, there appeared the first issue of *Index-Medicus, a Monthly Classified Record of the Current Medical Literature of the World*. The following year, volume 1 of the *Index-Catalogue of the Library of the Surgeon General's Office* was published. This project was a combined author and subject listing of monographs and periodical literature in the library. Fifteen years later, in 1895, volume 16 appeared, thus concluding the first series of the *Index-Catalogue*. The work contained a total of 176,364 author and 168,557 subject entries for books and pamphlets, as well as subject entries for 511,112 journal articles. William Welch, professor of pathology at the Johns Hopkins Medical School, claimed that the *Index-Catalogue* was America's greatest contributions to nineteenth-century medicine.^[1] The holdings of

the library in 1895—the year Billings retired—included 116,847 books and 191,598 pamphlets.

When Billings assumed charge of the library in 1865, it was housed in the Riggs Bank Building in Washington. In 1866, the collection was transferred to Ford's Theatre. These facilities, however, were also woefully inadequate, and, in 1887, the library and the Army Medical Museum moved into a newly constructed, three-story, red brick building that Billings and architect Adolph Cluss had designed on the Washington Mall. The library remained there until 1962, when it moved to new quarters in Bethesda.

The official name of the library, the Library of the Surgeon General's Office, remained in effect until 1922. In that year, it was changed to the Army Medical Library. Thirty years later, in 1952, the secretary of defense redesignated the library as the Armed Forces Medical Library, thus making it a joint agency of the three military departments. The last change came in 1956, when the institution officially became the National Library of Medicine and was transferred to what is now the Department of Health and Human Services. A source of detailed information about the development of the NLM is *A History of the National Library of Medicine*.^[2]

LEGISLATION

Senators Lister Hill (Alabama) and John F. Kennedy (Massachusetts) introduced the legislation that established the National Library of Medicine and authorized construction of necessary facilities. After wrangling about the location of the library, Congress finally passed the bill, and it was signed into law by President Eisenhower on August 3, 1956. The act established the library, created a board of regents to advise it, and left the question of where the library should be located up to the board. The legislation mandated that the library

- Acquire and preserve books, periodicals, prints, films, recordings, and other library materials pertinent to medicine
- Organize the materials...by appropriate cataloging, indexing, and bibliographical listing
- Publish...catalogs, indexes, and bibliographies
- Make available, through loans, photographic, or other copying procedures...materials in the library
- Provide reference and research assistance
- Engage in such other activities in furtherance of the purposes of this part as (the surgeon general) deems appropriate and the library's resources permit

The NLM Board of Regents advises the HHS secretary on matters of policy affecting the library. Ten regents, drawn from academia, the health sciences, librarianship, public life, and industry, are appointed by the secretary for 4-year terms. In addition to the appointed members, there are

nine ex officio members who are high-ranking federal officials in related fields, including the surgeons general of the Army, Navy, Air Force, and Public Health Service. Pioneering heart surgeon Michael E. DeBakey, whose persuasiveness in the halls of the Congress was instrumental in the passage of the NLM Act, was a member (and chair) of the first NLM Board of Regents. Reacting with dispatch to the act's provision for a new building, that original board, at their second meeting, recommended that a 10-acre tract on the campus of the National Institutes of Health in Bethesda, Maryland, be designated as the site of a new building for the National Library of Medicine. Five years later, in 1962, the library moved from the Washington Mall to its new \$7 million building in Bethesda.

The wording of the original legislation has been amended several times. The six functions listed above have been expanded with a seventh: "publicize the availability from the Library of the above products and services..."; and an eighth: "promote the use of computers and telecommunications..." Other congressional actions have had a profound effect on the library: the Medical Library Assistance Act (MLAA) of 1965, also championed by Dr. DeBakey, which created a program of grants and called for the establishment of a system of regional libraries, the joint resolution establishing the Lister Hill National Center for Biomedical Communications (1968), and the legislation creating the National Center for Biotechnology Information (1988), and the National Information Center on Health Services Research and Health Care Technology (1993).

Administration

The recommendations in a 1944 American Library Association report called *The National Medical Library: Report of a Survey of the Army Medical Library* would lay the foundation for the modern era of library practices. In the succeeding decades the Library would hire a Library Director, Brad Rogers, (1948) and ensure that he received training in library science; implement a collection development policy, with accompanying manual (1951), the first edition of the Army Medical Library Classification, a scheme for arrangement of books on medicine and pre-clinical sciences, designed for use in conjunction with the Library of Congress Classification, also as recommended by the *Report of a Survey* (1944). Rogers, though a physician selected from the Army Medical Corps, was sent to Columbia University to obtain a librarian's degree. In his role as Director of the Army Medical Library, Rogers was asked to modernize the library, provide it with more professional management and better organization and make it relevant to Congress.^[3] He oversaw the transition of the library from the military to the civilian sphere, the construction of a new building, and the tremendous job of moving the collection from Washington to Bethesda. It was Rogers who laid much of the groundwork for the

present-day National Library of Medicine, including the planning and early development of MEDLARS[®] (Medical Literature Analysis and Retrieval System) and the creation of the Medical Subject Headings (MeSH[®]) vocabulary, both of which figure prominently in the library's reputation as a leader in scientific communication.

Succeeding Rogers was Martin M. Cummings, a scientist, educator, and administrator, appointed in 1963. In the two decades under his guidance, the library assumed new responsibilities in a number of areas: a grants program, audiovisual facilities, research and development, specialized toxicology information services, and the introduction of a national online information retrieval services (MEDLINE[®] 1971). Cummings retired in late 1983, and in May 1984, Donald A.B. Lindberg, was named by the secretary of Health and Human Services to succeed him. Dr. Lindberg continues in that post today.

Lindberg, who at the time of his appointment was director of the Information Science Group and professor of pathology at the University of Missouri School of Medicine in Columbia, is an expert in the field of medical informatics—the use of computers and communications technology in medicine. Lindberg's tenure has been marked by a number of major initiatives: an extensive long-range planning process and publication of a detailed long-range plan for the library,^[4] a practical means of end-user searching of the NLM databases, the establishment at NLM of the National Center for Biotechnology Information and the National Information Center on Health Services Research and Health Care Technology, and the transition to the Internet and the Web as the primary distribution method for NLM information and data, the development of health information resources for the general public, and tremendous expansion in the amount of biomedical literature, scientific data, and health information that is freely available on the Web.

Organizational Structure

The NLM's organizational structure consists of an office of the director and six major operating components. The office of the director includes all the centralized management functions: planning, personnel, budget, contracting, purchasing, public communications, and equal employment opportunity. The director is assisted by a deputy director, a deputy director for research and education, an associate director for health information programs development, an assistant director for policy and development, and an associate director for administrative management. There are two assistant directors in the specialized areas of health services research information and high performance computing and communications (HPCC).

The major NLM components include the following:

- *Library Operations* (acquisition, cataloging, indexing, reference services, preservation, interlibrary loan, on-

line database management, health services research information, the National Network of Libraries of Medicine, and history of medicine)

- *Extramural Programs* (grant administration)
- *Specialized Information Services* (toxicology and environmental health information)
- *Lister Hill National Center for Biomedical Communications* (research and development)
- *National Center for Biotechnology Information* (programs in molecular biology information and sequence databases)
- *Office of Computer and Communications Systems*

Mission and Long Range Plans

The laws that shape and animate the National Library of Medicine are further informed by the Library's mission, and Long Range Plans, which add form and function to Library products and services. In the words of its Director, Donald A. B. Lindberg: "The purpose of the National Library of Medicine, flat out, is to acquire, organize and disseminate the biomedical knowledge of the world for the benefit of the public health. I mean, that's clear, and most people here understand that very well. It's one of the reasons we function efficiently."^[5] NLM had no long term plan when Lindberg arrived. "My predecessors were good, made wise decisions and needed no plan, but I needed one."^[6] Though a 1993 law would later require all agencies within the Department of Health and Human Services to have a strategic plan that defined its mission, goals, and the means by which it will measure its progress in addressing specific national problems, needs, or challenges related to its mission over the course of at least 5 years,^[7] NLM's first strategic plan was in place a full 6 years before that law, in 1987, and has followed with successive plans, to include the current Long Range Plan, *Charting the Course for the 21st Century: NLM's Long Range Plan 2006-2016* (<http://www.nlm.nih.gov/pubs/plan/>). NLM's current Long Range Plan has as its core four goals:

- Seamless, uninterrupted access to expanding collections of biomedical data, medical knowledge, and health information
- Trusted information services that promote health literacy, improve health outcomes, and reduce health disparities worldwide
- Integrated biomedical, clinical, and public health information systems that promote scientific discovery and speed the translation of research into practice
- A strong and diverse workforce for biomedical informatics research, systems development, and innovative service delivery

The library's commitment to meeting its legislative mandate, its mission, and its goals is visible in its print and

digital collections, along with a commitment to public access to scholarly publications; its databases, where bibliographic data, full-text, scientific data, and consumer health information are organized and made accessible to scientists, health professionals, and the public; vocabularies that underpin NLM's databases, and are also widely used in external product development; intramural research and development in computational biology, information retrieval, knowledge representation, natural language processing, imaging, and communications; grant funding of external informatics research and training; and through outreach, exhibits and training, where the library connects its products and services with the communities that need them.

COLLECTIONS

Print

In 2013, NLM's print collection held 20,869,244 items, comprising in part 863,182 monographs, 1871–present; 1,451,840 serials; and 17,372,682 manuscripts. The library broadly collects materials in the areas of biomedicine and the related areas of the life sciences, items that document the practice and teaching of medicine broadly defined, demonstrate how health services are organized, delivered, and financed, chronicle the development and implementation of policy that affects research and the delivery of health services, and illustrate the public perception of medical practice and public health. Since the mid-1990s, there have been added emphases and expansions in collecting in the subject areas of fundamental life sciences research; chemistry, physics, engineering; public health issues to include disaster management and bioterrorism; and complementary and alternative medicine.^[3,8] These areas correspond to relatively recent extensions of the Library's responsibilities in health services research, with the Congressionally directed founding of the National Center for Biotechnology Information in 1988, the National Information Center for Health Services Research and Technology in 1993, and the Disaster Information Management Research Center (DIMRC) in 2008. This broadening of scope reflects a goal set for NLM in the Board of Regents' Long Range Plan for 2006–2016. The print collection contains material in virtually every written language and from every country. The Library is guided in its selection process through its current Collection Development Manual (CDM), available online at: <https://www.nlm.nih.gov/tsd/acquisitions/cdm/index.html>, has antecedents in previous manuals dating back to 1951.

Historical

The judicious collecting of important medical works by nineteenth-century library director John Shaw Billings

resulted in the nucleus of the library's rare book and medical history collection. The ongoing accrual of rare books and manuscripts, as well as the acquisition of current monographs and periodicals for over a century, has made the library's holdings in the history of medicine one of the finest research collections in the world. The earliest medical work in the library is an Arabic manuscript of 1094. The earliest dated printed work is Rabanus Maurus, "*De sermonum proprietate*," published in Strasbourg in 1467. Altogether, the library owns over 580 incunabula. There are over 5000 volumes in the library printed in the sixteenth century; and nearly 65,000, including serials and theses, printed in the seventeenth and eighteenth centuries. The library holds not only most of the great landmark works of medicine, but also many less well-known works necessary for historical research, often in several successive editions and translations. Some of the volumes in the collection are the only known copies that survive.

Among the library's historical research collections are the modern manuscript items, dating from 1700. Many of these items were acquired over the past century as part of the general collecting of historical materials. However, to help preserve a record of the present and provide sources for future research in the history of medicine, the library has a "current manuscripts" acquisitions program as well. These new collections are, at times, supplemented by selected oral history interviews. The NLM also has a collection of some 60,000 pictures relating to the history of the health sciences and a significant collection of historical audiovisuals and motion pictures. The library's acquisition of significant manuscript materials, its collecting of rare books and monographs, and its publication of historical bibliographies help to give the scholar access to the history of medicine, just as other NLM functions supply bibliographical assistance for current research and information.

Preservation

The library has a committed focus on preservation of the collection in keeping with its national role as the library of last resort for other libraries, as well as its legislative mandate to preserve the books and other works it has acquired. One of the first steps in that process is collecting and maintaining the print collection. From 1986 to 2007, the Library microfilmed approximately 105,000 volumes of serial and monograph volumes printed on deteriorating paper.^[9] NLM stopped microfilming opting instead to provide digital access to selected collection holdings.

In 2011, the Library instituted a nationwide, cooperative, voluntary program with National Network of Libraries of Medicine (NN/LM) guaranteeing retention of clinically significant titles in print. The program, called MedPrint, identified approximately 250 journals as the primary set of materials to preserve in print. At the end of 2012, NLM had received 15 signed agreements from

institutions representing all eight NN/LM regions. Of the 250 titles identified in the MedPrint program, libraries across the country had made commitments to all but 10 titles. The goal of the program is to get commitments for 12 copies of each MedPrint title, with NLM's copy being the 13th. Thirty-nine of the 250 titles now have 12 or more commitments.^[10]

Collection Access

The library ensures the discoverability to its print collection through its online catalogs, LocatorPlus, and the NLM Catalog. In March 2013, NLM began using RDA: Resource Description and Access for all original cataloging of modern material, replacing the Anglo-American Cataloging Rules, second edition.

The print collection is available to the public onsite through the Library's History of Medicine and Main Reading Rooms. The print collection circulates beyond the Library's doors through the Library's interlibrary loan program, a service begun in 1870, when loan service was first established to make volumes from the Library's collections available to distant libraries and physicians.^[11] Onsite use of the print collection, though, is declining with in-person visits to the Main Reading Room decreasing throughout the late 1990s and 2000s.

In 2013, 1.4 million document requests were filled throughout the network using DOCLINE, the Library's own system for interlibrary loan requests and management. The number of interlibrary loan requests filled via DOCLINE peaked in 2002 at 3,038,934.^[12] In 2013, NLM instituted scan on demand, offering library users throughout the world the option of having a monograph, if copyright-free, fully scanned and a PDF copy sent to the requestor. A scanned copy of the monograph is then placed in NLM's digital repository.^[13] The results of a 2012 national survey of librarians who participate in DOCLINE largely attributed the decline in interlibrary loans to the availability of materials online and though not stated, presumably available online without charge; and the greater availability of online journals through package deals that even smaller libraries could afford, or participate in through consortia. Changes in how users interact with the collection are seen most readily in the inception and growth of the Library's digital collections.^[12]

Public Access to Journal Literature

Launched in February 2000, PubMed Central® (PMC), a free archive of biomedical and life sciences journal literature, was developed and is managed by NLM's National Center for Biotechnology Information (NCBI). In keeping with NLM's legislative mandate to collect and preserve the biomedical literature, PMC serves as a digital counterpart to NLM's extensive print journal collection. In 2012, PubMed Central held 2,540,2952 articles and 1,149

journal titles.^[14] The NIH Public Access Policy ensures that the public has access to the published results of NIH funded research. It requires scientists to submit final peer-reviewed journal manuscripts that arise from NIH funds to the digital archive PubMed Central immediately upon acceptance for publication. To help advance science and improve human health, the Policy requires that these papers are accessible to the public on PubMed Central no later than 12 months after publication.

Digital Collections

NLM also maintains "Digital Collections," a free online archive of nonjournal biomedical resources. All the content in Digital Collections is in the public domain and freely available worldwide. Digital Collections provides preservation of and unique access to NLM's rich, historical resources. In 2012, the Digital Collections Repository held 6979 texts and 70 audiovisuals. The Digital Collections encompass subject areas of Medicine in the Americas, 1620–1920; Cholera Online, 1817–1900; NLM Publications and Productions; Tropical Disease Motion Pictures; The Public Health Film Goes to War; and the NIH Annual Reports.^[15]

In 1998, NLM introduced the web site "Profiles in Science," a web site that makes the archival collections of prominent biomedical scientists available to the public through modern digital technology.^[16] The collections have been donated to the NLM and contain published and unpublished materials, including books, journal volumes, pamphlets, diaries, letters, manuscripts, photographs, and audio tapes and other audiovisual materials. The collection includes famous American scientists and public health figures such as Oswald Avery and C. Everett Koop, plus Nobel laureates Christian Anfinsen, Julius Axelrod, Joshua Lederberg, and Martin Rodbell.^[16]

Born Digital

Started as a pilot in 2009, "Health and Medicine Blogs," is a unique repository of archived health blogs, developed by NLM in collaboration with the Internet Archive. Collected blogs feature the perspectives of physicians, nurses, hospital administrators, and other health professionals. The Library has also collected blogs of patients chronicling their experiences with conditions such as cancer, diabetes, and multiple sclerosis. These blogs illustrate the public perception of medical practice, provide insight into the health care environment, and document medical innovations and medical education in the twenty-first century.^[17]

DATABASES

Ever since the Library's earliest days, it had dual roles, one in which it built and maintained a print collection, and

one in which it indexed the medical literature, making it accessible at the article level for not just on-site users, but to users throughout the world, through the publication of the indexes, the *Index-Catalogue* and the *Index Medicus*. From *Index Medicus* to MEDLINE/PubMed[®], NLM has continued its role in aiding users worldwide in the discovery of information contained in the biomedical literature, while expanding its services to include other kinds of information and data. During the first 25 years of its online services, NLM charged modest fees to recover the cost of online access via commercial telecommunications networks. When Internet access became prevalent in the mid-1990s, NLM was able to make its databases freely available.

MEDLINE/PubMed[®]

Currently, MEDLINE/PubMed is the premier biomedical database in the world, providing free access to MEDLINE, NLM's database of citations and abstracts in the fields of medicine, nursing, dentistry, veterinary medicine, health care systems, and preclinical sciences. PubMed links to full-text articles found in PubMed Central or at publisher web sites, and other related resources.^[18] In 2013, PubMed held 23 million records, 5,669 journals currently indexed for MEDLINE, 61% of the citations linking to full-text, 18% linked to free full-text; and in a typical day 3.5 million Web searches are recorded (730,000 users), 5.5 million record views (1.7 million users), and 75,000 mobile searches (18,000 users).^[19] The Entrez system that delivers PubMed is developed and maintained by the National Center for Biotechnology Information (NCBI). NCBI improves users' search experience following a Discovery Initiative model, using automated methods to draw users' attention to related data that do not necessarily appear as part of the original search. Various "ads" on results pages provide links to related articles and citations, queries, gene names, gene symbols, free full text, protein and nucleotide records, and accession numbers.^[20] In 2013, NCBI debuted PubMed Commons (<http://test.ncbi.nlm.nih.gov/pubmedcommons>), a new system that enables researchers who are PubMed authors to share their opinions about scientific publications indexed in the PubMed database.^[21]

Today NLM has over 295 databases, resources, and application programming interfaces (APIs), on biomedicine, toxicology, hazardous substances, lactation medicine, household products, genes, and consumer health. MedlinePlus Connect, a system for linking electronic health records (EHR) systems to NLM consumer health content, and ClinicalTrials.gov, with detailed information on human subject studies, are two resources that have significant impact on information for patients, and patient care. A list of NLM databases, resources, and APIs can be found on this page: http://wwwcf2.nlm.nih.gov/nlm_eresources/eresources/search_database.cfm

MedlinePlus Connect

MedlinePlus Connect, launched in 2010, is a system to link patient portals, electronic health record (EHR) systems, and health IT systems to consumer health information from MedlinePlus.gov. MedlinePlus Connect meets the meaningful use requirement of the HITECH Act (Health Information Technology for Economic and Clinical Health), part of the American Recovery and Reinvestment Act (ARRA) of 2009, which seeks to improve American health care delivery and patient care through an unprecedented investment in Health IT (HIT). The provisions of the HITECH Act are specifically designed to work together to provide the necessary assistance and technical support to providers, enable coordination and alignment within and among states, establish connectivity to the public health community in case of emergencies, and assure the workforce is properly trained and equipped to be meaningful users of certified Electronic Health Records (EHRs). Meaningful use is a Center for Medicare and Medicaid Services (CMS) payment incentive program for the use of certified EHRs by hospitals and providers in a way that meets specific requirements.^[22]

MedlinePlus

MedlinePlus Connect uses the MedlinePlus web site, a popular portal to consumer health information. The site offers authoritative, up-to-date health information, without advertisements, and is available anytime, anywhere for free.^[23] A Spanish-language version, MedlinePlus en español (<http://medlineplus.gov/spanish>) is also available. MedlinePlus pages contain carefully selected links to Web resources with health information on over 900 topics. MedlinePlus follows a list of guidelines for the inclusion of web sites. The MedlinePlus health topic pages include links to current news on the topic and related information. The public can also find preformulated searches of the MEDLINE/PubMed database, which allow them to find references to latest health professional articles on a topic. The A.D.A.M. medical encyclopedia brings health consumers an extensive library of medical images and videos, as well as over 4000 articles about diseases, tests, symptoms, injuries, and surgeries. Drug and supplement information is available from the American Society of Health-System Pharmacists (ASHP) via AHFS[®] Consumer Medication Information, and Natural Medicines Comprehensive Database Consumer Version.^[24]

ClinicalTrials.gov

ClinicalTrials.gov, launched in February 2000 to implement provisions of the Food and Drug Administration Modernization Act (Public Law 105-115), that required creation of a centralized, consumer-friendly online listing of clinical trials of drugs for serious and life-threatening

conditions. In an effort spearheaded by NLM, the National Institutes of Health (NIH) developed this site in collaboration with all NIH Institutes and the U.S. Food and Drug Administration (FDA). The database now has more than 160,000 clinical trials and observational studies, with studies in locations in all 50 states and 185 countries and includes summary results tables for more than 11,000 trials. It is the only public source of results data for many trials. In 2007, the FDA Amendments Act mandated deposit of registration data for an expanded set of trials of FDA regulated drugs, biologics, and devices and deposit of summary results for trials of approved products. The ClinicalTrials.gov results database was launched in September 2008 to implement the clinical trials provisions of this law. Submission of adverse event information was optional when the results database was released and became mandatory in September 2009. In 2013, ClinicalTrials.gov saw 95 million page views per month, 60,000 visitors per day.

MEDICAL TERMINOLOGIES

NLM is home to a number of medical terminologies that it creates and curates for use in its own products, and for use by others in commercial and free products. A standardized medical terminology is often used within a database in such a way that it enables users to interact with the database using their own words and have their words connect with other words like theirs (synonyms, or ones with the same meaning) using the controlled vocabulary. NLM also licenses SNOMED CT[®], a clinical terminology, designated as a U.S. standard for electronic health information exchange in Interoperability Specifications produced by the Healthcare Information Technology Standards Panel.^[25]

Medical Subject Headings (MeSH)

MeSH is the National Library of Medicine's controlled vocabulary thesaurus. It consists of sets of terms naming descriptors in a hierarchical structure that permits searching at various levels of specificity. The MeSH thesaurus is used by NLM for indexing articles for the MEDLINE/PubMED database and for the NLM-produced database that includes cataloging of books, documents, and audiovisuals acquired by the Library. MeSH, in machine-readable form, is provided at no charge via electronic means. MeSH descriptors are arranged in both an alphabetic and a hierarchical structure.

The MeSH thesaurus is used by NLM for indexing articles from 5600 of the world's leading biomedical journals for the MEDLINE[®]/PubMed database. It is also used for the NLM-produced database that includes cataloging of books, documents, and audiovisuals acquired by the Library. Each bibliographic reference is

associated with a set of MeSH terms that describe the content of the item. Similarly, search queries use MeSH vocabulary to find items on a desired topic.^[26,27]

Unified Medical Language System (UMLS)

The National Library of Medicine (NLM) produces the Unified Medical Language System[®] (UMLS[®]) to facilitate the development of computer systems that behave as if they “understand” the meaning of the language of biomedicine and health. As part of the UMLS, NLM produces and distributes the UMLS Knowledge Sources (databases) and associated software tools (programs) for use by system developers in building or enhancing electronic information systems that create, process, retrieve, integrate, and/or aggregate biomedical and health data and information, as well as in informatics research.

By design, the UMLS Knowledge Sources are not limited to particular applications; they are multipurpose. Developers will find that they can be applied in systems that perform a range of functions involving one or more types of information, e.g., patient records, scientific literature, guidelines, public health data. The associated UMLS software tools assist developers in customizing or using the UMLS Knowledge Sources for particular purposes. The Unified Medical Language System (UMLS) integrates and distributes key terminology, classification and coding standards, and associated resources to promote creation of more effective and interoperable biomedical information systems and services, including electronic health records. All UMLS Knowledge Sources and associated software tools are free of charge to U.S. and international users. There are three UMLS Knowledge Sources: the Metathesaurus[®], the Semantic Network, and the SPECIALIST Lexicon. The Metathesaurus contains over 150 source vocabularies, such as MeSH[®], RxNorm, SNOMED CT[®], ICD-9-CM, ICD-10-CM, CPT[®], and LOINC[®]. Many of the vocabularies are designated as U.S. health standards for electronic health records.^[25]

RxNorm

RxNorm is two things: a normalized naming system for generic and branded drugs; and a tool for supporting semantic interoperation between drug terminologies and pharmacy knowledge base systems. RxNorm is a controlled vocabulary for drugs, providing normalized names and codes for clinical drugs and links its names to many of the drug vocabularies commonly used in pharmacy management and drug interaction software, including those of First Databank, Micromedex, MediSpan, Gold Standard Alchemy, and Multum. By providing links between these vocabularies, RxNorm can mediate messages between systems not using the same software and vocabulary. RxNorm is the U.S. medication standard for health data exchange.^[25,28]

SNOMED CT

SNOMED Clinical Terms (SNOMED CT) is an extensive clinical terminology that was formed by the merger, expansion, and restructuring of SNOMED RT[®] (Reference Terminology) and the United Kingdom National Health Service (NHS) Clinical Terms (also known as the Read Codes). It is the most comprehensive clinical vocabulary available in English (or any language). SNOMED CT is concept-oriented and has an advanced structure that meets most accepted criteria for a well-formed, machine-readable terminology. It has been designated as a U.S. standard for electronic health information exchange in Interoperability Specifications produced by the Healthcare Information Technology Standards Panel and has also been adopted for use by the U.S. Federal Government, through the Consolidated Health Informatics (CHI) Initiative, for several clinical domains.^[29]

Coordination of Clinical Terminologies

NLM is the central coordinating body for clinical terminology standards within the Department of Health and Human Services (HHS). NLM works closely with the Office of the National Coordinator for Health Information Technology (ONC) to ensure NLM's efforts are aligned with the goal of the President and HHS Secretary for the nationwide implementation of an interoperable health information technology infrastructure to improve the quality and efficiency of health care. NLM supports, licenses, or develops key Clinical Vocabularies identified for Meaningful Use and HIPAA transactions: SNOMED CT[®], LOINC[®], and RxNorm. NLM represents the United States on matters related to the structure and content of SNOMED CT, as member of the International Health Terminology Standards Development Organisation (IHTSDO[®]). NLM provides uniform distribution for more than 150 clinical vocabulary standards and HIPAA administrative code sets through the UMLS Metathesaurus.^[30]

Value Set Authority Center

In 2012, in cooperation with the Office of the National Coordinator for Health Information Technology, and the Center for Medicare and Medicaid Services (CMS), NLM launched the Value Set Authority Center (VSAC).^[31] VSAC currently serves as the authority and central repository for the official versions of value sets that support Meaningful Use 2014 Clinical Quality Measures (CQMs). The VSAC provides search, retrieval, and download capabilities through a Web interface and APIs. The VSAC will maintain and update the value sets consistent with the overall process for maintaining and updating the 2014 CQMs themselves. Through the VSAC, NLM draws upon the UMLS Metathesaurus and its responsibility as the central coordinating body for clinical terminology

standards within the Department of Health and Human Services (HHS) to assure the on-going validity and accuracy of the value sets. In the future, the VSAC will provide authoring tools for users to create value sets.^[20]

RESEARCH AND DEVELOPMENT

There are two divisions within NLM that conduct research: the Lister Hill National Center for Biomedical Communication (LHNCBC) and the National Center for Biomedical Information (NCBI). Lister Hill Center conducts and supports research and development in high quality imagery, medical language processing, high-speed access to biomedical information, intelligent database systems development, multimedia visualization, knowledge management, data mining, machine-assisted indexing, and electronic health records to facilitate patient-centric care. NCBI conducts research in basic and applied research in computational, mathematical, and theoretical problems in molecular biology and genetics; and data representation and analysis, including the development of computer-based systems for the storage, management, and retrieval of knowledge relating to molecular biology, genetics, and biochemistry. Both Lister Hill Center and NCBI have Boards of Scientific Counselors (BOSC) who review the work of their intramural researchers; and both offer training opportunities for post-doctoral fellows. NLM's Board of Regents delineated specific research directions for NLM overall and Lister Hill Center and NCBI in particular, in the 2006–2016 Long Range Plan, in Goal 3: Integrated biomedical, clinical, and public health information systems that promote scientific discovery and speed the translation of research into practice.

NCBI

Within the Long Range Plan, NCBI was specifically charged with developing linked databases for discovering relationships between clinical data, genetic information, and environmental factors and that NCBI should

- Lead the development of repositories of information on human variation that will be essential tools for discovering the associations between genes and disease
- Continue to be the computational and database focal point in a trans-NIH program to connect clinical and genotypic data from large, long-term studies
- Assume a leadership role in this effort (make data available, protect privacy, and inform public) and thus contribute to the transformation of clinical, genomic, and environmental information into better evidence-based medicine and improved patient care

NCBI's molecular biology information resources are based on sequence repositories upon which curated and annotated sets of data resources are built. Information ranges from genetic sequence data to entire genomes, protein sequences and structures to chemical structures and assays, as well as clinical data paired with genotypes. The primary source for NCBI sequence data is GenBank, the NIH genetic sequence database. GenBank is an annotated collection of all publicly available DNA sequences.^[3] GenBank is part of the International Nucleotide Sequence Database Collaboration, which comprises the DNA DataBank of Japan (DDBJ), the European Molecular Biology Laboratory (EMBL), and GenBank at NCBI. These three organizations exchange data on a daily basis.^[20] Eleven taxonomy divisions within GenBank contain sequences for over 380,000 species.^[20]

LHNCBC

Within the Long Range Plan, the Lister Hill Center was specifically charged with promoting the development of next-generation electronic health records to facilitate patient-centric care, clinical research and public health. Additionally, the Plan encouraged NLM and Lister Hill to

- Enhance these efforts in response to specific U.S. government priorities and feedback from those attempting to implement standards in current electronic health records and personal health records, regional health information exchanges, clinical research systems, and public health applications
- Build on its long development and policy studies related to electronic health records by promoting work to define and develop the next generation of electronic health records (EHR)
- Promote development and use of advanced electronic representations of biomedical knowledge in conjunction with electronic health records
- Continue to promote research and development on robust and scaleable approaches to synthesizing, representing, updating, and deploying electronic knowledge and decision algorithms for use in conjunction with electronic health records

In 2008, Lister Hill debuted an NLM Personal Health Record (PHR), with an early version aiming to help individuals who are caring for their elderly parent(s) and/or young children. The goal of the NLM Personal Health Record is to help individuals manage health care for themselves and their relatives. The PHR is intended to serve as a test-bed for patient-specific and reminder-based consumer education information, validating and improving NLM clinical vocabularies, studying consumers' use of PHR systems, studying the potential of PHR-based educational reminder systems to improve prevention, and as a potential vehicle for gathering information during clinical

trials. The PHR supports the entry and tracking of key measurements, test results, prescriptions, problems, immunizations, and future health appointments.^[33]

Also in 2008, LHNCBC researchers initiated an effort to develop an open source text de-identification tool. The tool, called Clinical Text De-identification (CTD) system, is software that complies with the privacy rule of the Health Insurance Portability and Accountability Act (HIPAA). The rule requires the removal of 18 individually identifiable health information elements that could be used to identify the individual, the individual's relatives, employers, or household members. In 2011, LHNCBC researchers conducted a study of the CTD tool against four state-of-the-art systems and found that the CTD was superior in the detection of personal names in clinical reports than the methods of the other four systems.^[33]

Extramural Programs

The Extramural Programs Division (EP) administers extramural grant programs for NLM as authorized by the Medical Library Assistance Act (MLAA) and Public Health Service Act. EP's first grant awards were issued in 1965. Funds are expended as grants-in-aid to the extramural community in support of the Library's mission. Review and award procedures conform to NIH policies. EP awards several categories of grants, all of which pertain to biomedical informatics and the management and dissemination of biomedical knowledge. Biomedical informatics research applies computer and information sciences to improve the access, storage, retrieval, management, dissemination, and use of biomedical information. Applications are received through "parent" NIH funding announcements or through special funding opportunity announcements issued by EP. Each year, NLM makes new and/or continuing awards in these five grant categories: Research Projects, Resources, Career Development, Research Career Training, and Small Business Research & Development. NLM's EP FY2012 base budget for grant awards was \$44,281,000, the same amount as in FY2011. One hundred thirty-seven new and continuing awards were made with NLM's appropriated funds. An additional \$3.3 million in co-funding was received for 11 awards from other NIH and Department of Health and Human Services (DHHS) sources. FY2012 funds were awarded to 35 organizations in 32 states.^[33]

OUTREACH, EXHIBITIONS, AND TRAINING

NLM conducts its outreach primarily through the National Network of Libraries of Medicine (NN/LM), its network of over 6000 organizations throughout the country. These include academic medical libraries, hospital, pharmaceutical and other special health sciences libraries, information centers, public libraries, and community-based

organizations with an interest in promoting access to health information. The NN/LM was created through the Medical Library Assistance Act of 1965 (Public Law 89-291), which both authorized NLM's extramural programs of grant assistance to improve the nation's medical library and health communication resources as well as establishing the Regional Medical Library Network (now called the National Network of Libraries of Medicine). The introduction of an extension of the National Library of Medicine to the rest of the country through the NN/LM caused some contention at first among health sciences libraries, but in time the creation of the Network only served to strengthen the ties to health sciences libraries and extend NLM's influence.^[34] Other offices and divisions that conduct outreach are the Office of Health Information Program Development, which sponsors specialized programs in outreach to elementary through high school students in choosing careers in health; a program called VIVA!, peer tutoring for the Latino population in Texas and elsewhere; and Native American outreach through NLM representation at American Indian Pow-Wows through the Mid-Atlantic area. The division of Specialized Information Services (SIS) also conducts outreach, focusing on reaching special populations of minority populations through its United Negro College Funds Special Programs (UNCFSP) HBCU Access Project; debuting an outreach effort in 2012 to Black Greek Letter Organizations to combat health disparities; training in the use of NLM resources through partnerships with minority health professional organizations; and through the development of special population web sites focusing on health information including the American Indian Health Web Portal, Women's Health Resources, Arctic Health Web Site, and the Refugee Health Information Network (RHIN).^[33]

National Network of Libraries of Medicine (NN/LM)

Today, the NN/LM is comprised of eight regions throughout the country, each led by a Regional Medical Library (RML), through a contract awarded every 5 years from the National Library of Medicine. The current Regional Medical Libraries are based at the University of Massachusetts, University of Pittsburgh, University of Maryland, Baltimore, Houston Academy of Medicine/Texas Medical Center, University of Utah, University of California, Los Angeles, University of Illinois at Chicago, and the University of Washington. These Regional Medical Libraries employ staff that vary in size from five to eleven, and extend the National Library of Medicine's reach and assistance to medical libraries through education and training and outreach, and the reduction of health disparities.

With the assistance of other NN/LM members, the RMLs do most of the exhibits and demonstrations of NLM products and services at health professional,

consumer health, and general library association meetings around the country. In FY2012, NLM and NN/LM services were exhibited at 29 national and 281 regional, state, and local conferences across the United States.

RMLs and other network members conduct many special projects to reach underserved health professionals and to improve the public's access to high quality health information. Virtually all of these projects involve partnerships between health sciences libraries and other organizations, including public libraries, public health departments, professional associations, schools, churches, and other community-based groups. In FY2012, the NN/LM initiated 232 outreach projects which target rural and inner city communities and special populations in 37 states, the District of Columbia, U.S. Virgin Islands, Puerto Rico, and Guam.^[33]

DIMRC

A relatively recent addition to NLM's outreach efforts was the creation of a Disaster Information Management Research Center. Recognizing the untapped potential of libraries, librarians, and information services to aid in the nation's disaster management efforts, the Long Range Plan (2006–2016) recommended the creation of a Disaster Information Management Research Center to help with national emergency preparedness, response, and recovery efforts. As part of NLM's SIS division, DIMRC is tasked with the collection, organization and dissemination of health information resources and informatics research related to disasters of natural, accidental, or deliberate origin. NLM has a long history of providing health information to prepare for and respond to all types of disasters, and has developed a number of tools and advanced information services designed for disaster and emergency. NLM provided information for the Bhopal, India gas leak in 1984 and helped create local disaster information centers following Hurricane Mitch in Central America. NLM's Hazardous Substances Data Bank (HSDB[®]), a comprehensive toxicology database, provides the framework for the Wireless Information System for Emergency Responders (WISER[®]), a resource used by emergency responders to assist with the management of chemical, radiological, and biological emergencies. WISER was used in Louisiana after Hurricane Katrina, and in Iraq to help identify potentially toxic substances. More recently, NLM assisted public health officials responding to H1N1 influenza, earthquakes in Haiti and Chile, the Gulf of Mexico oil spill, and the Japanese radiation event, by providing timely, evidence-based information.^[35]

Exhibitions

NLM hosts major exhibitions in its rotunda. Designed to appeal to the interested public as well as the

specialist, these exhibitions highlight the Library's resources and are an important part of NLM's outreach program. The most recent exhibition is *Native Voices: Native Peoples' Concepts of Health and Illness*, exploring the interconnectedness of wellness, illness, and cultural life for Native Americans, Alaska Natives, and Native Hawaiians. Through the extensive use of interviews and media, visitors discover how Native concepts of health and illness are closely tied to the concepts of community, spirit, and the land. NLM sent out 25 copies of 12 exhibition titles, to 156 host venues, most in libraries, in 43 states, and five international locations during 2012. Host venues and their audiences had positive and favorable responses to the traveling exhibition program. All exhibitions also feature an online counterpart as well.^[33]

Training

The fourth goal of the Long Range Plan 2006–2016 is a strong and diverse workforce for biomedical informatics research, systems development, and innovative service delivery. NLM meets this goal in part through its training programs, from its early career fellowship program for recent library science graduates, to mid-career training opportunities in biomedical informatics, funded support for academic training in biomedical informatics, fellowships in medical informatics and senior level career support for health sciences librarians preparing for director-level positions in academic health sciences libraries.^[36] Many health sciences library directors, distinguished informatics researchers, and leaders in health information technology are graduates of these programs.

CONCLUSIONS

As the National Library of Medicine moves more fully into the twenty-first century, it can see the fulfillment of many initiatives begun in the last century: the greater availability of the scholarly literature through online repositories, and through its own web sites of digital collections and the integration of and use of its databases and terminologies into others' work through the creation of apps, and repurposing of terminologies used in other settings. The National Library of Medicine also continues to chart its future, through its research and development branches, the awarding of extramural grants, and through its investment in the future in training a biomedical workforce. The underlying commitment of the National Library of Medicine remains the same: the acquisition, organization, and preservation of the biomedical literature for the public.

Natural Language Processing for Information Retrieval

Elizabeth D. Liddy

School of Information Studies, Syracuse University, Syracuse, New York, U.S.A.

Abstract

Natural language processing (NLP) is the computerized approach to analyzing text that is based on both a set of theories and a set of technologies. Although NLP is a relatively recent area of research and application, compared with other information technology approaches, there have been sufficient successes to date that suggest that NLP-based information access technologies will continue to be a major area of research and development in information systems now and into the future.

INTRODUCTION

Natural language processing (NLP) is the computerized approach to analyzing text that is based on both a set of theories and a set of technologies. And, being a very active area of research and development, there is not a single agreed-upon definition that would satisfy everyone, but there are some aspects, which would be part of any knowledgeable person's definition. I offer the following definition: Natural language processing is a theoretically motivated range of computational techniques for analyzing and representing naturally occurring texts at one or more levels of linguistic analysis for the purpose of achieving human-like language processing for a range of tasks or applications.

Several elements of this definition can be further detailed. First, the imprecise notion of "range of computational techniques" is necessary because there are multiple methods or techniques from which to choose to accomplish a particular type of language analysis.

"Naturally occurring texts" can be of any language, mode, genre, etc. The texts can be oral or written. The only requirement is that they be in a language used by humans to communicate to one another. In addition, the text being analyzed should not be specifically constructed for the purpose of the analysis, but rather that the text be gathered from actual usage.

The notion of "levels of linguistic analysis" (to be further explained in the section titled "Levels of Natural Language Processing") refers to the fact that there are multiple types of language processing known to be at work when humans produce or comprehend language. It is thought that humans normally use all of these levels because each level conveys different types of meaning. But various NLP systems use different levels or combinations of levels of linguistic analysis, and this is seen in the differences among various NLP applications. This also leads to much confusion on the part of nonspecialists as to what NLP really is, because a system that uses any

subset of these levels of analysis can be said to be an NLP-based system. The difference between them, therefore, may actually be whether the system uses "weak" NLP or "strong" NLP.

"Human-like language processing" reveals that NLP is considered a discipline within artificial intelligence (AI). And although the full lineage of NLP does depend on a number of other disciplines, because NLP strives for human-like performance, it is appropriate to consider it an AI discipline.

"For a range of tasks or applications" points out that NLP is not usually considered a goal in and of itself, except perhaps for AI researchers. For others, NLP is the means for accomplishing a particular task. Therefore, you have Information Retrieval (IR) systems that use NLP, as well as machine translation (MT), question-answering, etc.

Goal

The goal of NLP as stated above is "to accomplish human-like language processing." The choice of the word "processing" is very deliberate and should not be replaced with "understanding." For although the field of NLP was originally referred to as natural language understanding (NLU) in the early days of AI, it is well agreed today that although the goal of NLP is true NLU, that goal has not yet been accomplished. A full NLU system would be able to:

1. Paraphrase an input text.
2. Translate the text into another language.
3. Answer questions about the contents of the text.
4. Draw inferences from the text.

Although NLP has made serious inroads into accomplishing goals 1–3, the fact that NLP systems cannot, of themselves, draw inferences from text, NLU still remains the goal of NLP.

There are more practical goals for NLP, many related to the particular application for which it is being used. For example, an NLP-based IR system has the goal of providing more precise, complete information in response to a user's real information need. The goal of the NLP system here is to represent the true meaning and intent of the user's query, which can be expressed as naturally in everyday language as if they were speaking to a reference librarian. In addition, the contents of the documents that are being searched will be represented at all their levels of meaning so that a true match between need and response can be found, no matter how either are expressed in their surface form.

Origins

As most modern disciplines, the lineage of NLP is indeed mixed and still today has strong emphases by different groups whose backgrounds are more influenced by one or another of the disciplines. Key among the contributors to the discipline and practice of NLP are the following: Linguistics focuses on formal, structural models of language and the discovery of language universals—in fact, the field of NLP was originally referred to as computational linguistics; computer science is concerned with developing internal representations of data and efficient processing of these structures; and cognitive psychology looks at language usage as a window into human cognitive processes and has the goal of modeling the use of language in a psychologically plausible way.

Divisions

Although the entire field is referred to as natural language processing, there are in fact two distinct focuses: language processing and language generation. The first of these refers to the analysis of language for the purpose of producing a meaningful representation, whereas the latter refers to the production of language from a representation. The task of NLP is equivalent to the role of reader/listener, whereas the task of natural language generation is that of the writer/speaker. Although much of the theory and technology are shared by these two divisions, natural language generation also requires a planning capability. That is, the generation system requires a plan or model of the goal of the interaction to decide what the system should generate at each point in an interaction. We focus on the task of natural language analysis, because this is most relevant to library and information science studies.

Another distinction is traditionally made between language understanding and speech understanding. Speech understanding starts with, and speech generation ends with, oral language and, therefore, rely on the additional fields of acoustics and phonology. Speech understanding focuses on how the “sounds” of language as picked up by the system in the form of acoustical waves are transcribed

into recognizable morphemes and words. Once in this form, the same levels of processing, which are used on written text are used. All of these levels, including the phonology level, are covered in “Levels of Natural Language Processing”; however, the emphasis throughout is on language in the written form.

BRIEF HISTORY OF NATURAL LANGUAGE PROCESSING

Research in natural language processing has been going on for several decades dating back to the late 1940s. Machine translation (MT) was the first computer-based application related to natural language. Although Weaver and Booth^[1,2] started one of the earliest MT projects in 1946 on computer translation based on expertise in breaking enemy codes during World War II, it was generally agreed that it was Weaver's memorandum of 1949 that brought the idea of MT to general notice and inspired many projects.^[3] He suggested using ideas from cryptography and information theory for language translation. Research began at various research institutions in the United States within a few years.

Early work in MT took the simplistic view that the only differences between languages resided in their vocabularies and the permitted word orders. Systems developed from this perspective simply used dictionary lookup for appropriate words for translation and reordered the words after translation to fit the word-order rules of the target language, without taking into account the lexical ambiguity inherent in natural language. This produced poor results. The apparent failure made researchers realize that the task was a lot harder than anticipated, and they needed a more adequate theory of language. However, it was not until 1957 when Chomsky^[4] published *Syntactic Structures* introducing the idea of generative grammar, did the field gain better insight into whether or how mainstream linguistics could help MT.

During this period, other NLP application areas began to emerge, such as speech recognition. The language-processing community and the speech community then were split into two camps with the language-processing community dominated by the theoretical perspective of generative grammar and hostile to statistical methods, and the speech community dominated by statistical information theory^[5] and hostile to theoretical linguistics.^[6]

Because of the developments of the syntactic theory of language and parsing algorithms, there was such enthusiasm in the 1950s that people believed that fully automatic high-quality translation systems^[2] would be able to produce results indistinguishable from those of human translators, and such systems should be in operation within a few years. It was not only unrealistic, given the then-available linguistic knowledge and computer systems, but also impossible in principle.^[3]

The inadequacies of then-existing systems, and perhaps accompanied by the overenthusiasm, led to the ALPAC (Automatic Language Processing Advisory Committee of the National Academy of Science–National Research Council) report of 1966.^[17] The report concluded that MT was not immediately achievable and recommended it not be funded. This had the effect of halting MT and most work in other applications of NLP at least within the United States.

Although there was a substantial decrease in NLP work during the years after the ALPAC report, there were some significant developments, both in theoretical issues and in construction of prototype systems. Theoretical work in the late 1960s and early 1970s focused on the issue of how to represent meaning and developing computationally tractable solutions that the then-existing theories of grammar were not able to produce. In 1965, Chomsky^[8] introduced the transformational model of linguistic competence. However, the transformational generative grammars were too syntactically oriented to allow for semantic concerns. They also did not lend themselves easily to computational implementation. As a reaction to Chomsky's theories and the work of other transformational generativists, case grammar of Fillmore,^[9] semantic networks of Quillian,^[10] and conceptual dependency theory of Schank^[11] were developed to explain syntactic anomalies and provide semantic representations. Augmented transition networks of Woods^[12] extended the power of phrase-structure grammar by incorporating mechanisms from programming languages such as LISP. Other representation formalisms included Wilks' preference semantics^[13] and Kay's functional grammar.^[14]

Alongside theoretical development, many prototype systems were developed to demonstrate the effectiveness of particular principles. Weizenbaum's ELIZA^[15] was built to replicate the conversation between a psychologist and a patient, simply by permuting or echoing the user input. Winograd's SHRDLU^[16] simulated a robot that manipulated blocks on a tabletop. Despite its limitations, it showed that natural language understanding was indeed possible for the computer.^[17] PARRY^[18] attempted to embody a theory of paranoia in a system. Instead of single keywords, it used groups of keywords and used synonyms if keywords were not found. LUNAR was developed by Woods^[19] as an interface system to a database that consisted of information about lunar rock samples using augmented transition network and procedural semantics.^[20]

In the late 1970s, attention shifted to semantic issues, discourse phenomena, and communicative goals and plans.^[21] Grosz^[22] analyzed task-oriented dialogues and proposed a theory to partition the discourse into units based on her findings about the relation between the structure of a task and the structure of the task-oriented dialogue. Mann and Thompson^[23] developed Rhetorical Structure Theory, attributing hierarchical structure to

discourse. Other researchers have also made significant contributions, including Hobbs and Rosenschein,^[24] Polanyi and Scha,^[25] and Reichman.^[26]

This period also saw considerable work on natural language generation. McKeown's discourse planner TEXT^[27] and McDonald's response generator MUMMBLE^[28] used rhetorical predicates to produce declarative descriptions in the form of short texts, usually paragraphs. TEXT's ability to generate coherent responses on-line was considered a major achievement.

In the early 1980s, motivated by the availability of critical computational resources, the growing awareness within each community of the limitations of isolated solutions to NLP problems,^[21] and a general push toward applications that worked with language in a broad, real-world context,^[6] researchers started reexamining nonsymbolic approaches that had lost popularity in early days. By the end of the 1980s, symbolic approaches had been used to address many significant problems in NLP, and statistical approaches were shown to be complementary in many respects to symbolic approaches.^[21]

In the last 10 years of the millennium, the field was growing rapidly. This can be attributed to the following: 1) increased availability of large amounts of electronic text; 2) availability of computers with increased speed and memory; and 3) the advent of the Internet. Statistical approaches succeeded in dealing with many generic problems in computational linguistics such as part-of-speech identification, word sense disambiguation, etc. and have become standard throughout NLP.^[29] Researchers of NLP are now developing next-generation NLP systems that deal reasonably well with general text and account for a good portion of the variability and ambiguity of language.

LEVELS OF NATURAL LANGUAGE PROCESSING

The most explanatory method for presenting what actually happens within a natural language processing system is by means of the "levels of language" approach. This is also referred to as the synchronic model of language and is distinguished from the earlier sequential model, which hypothesizes that the levels of human language processing follow one another in a strictly sequential manner. Psycholinguistic research suggests that language processing is much more dynamic, because the levels can interact in a variety of orders. Introspection reveals that we frequently use information we gain from what is typically thought of as a higher level of processing to assist in a lower level of analysis. For example, the pragmatic knowledge that the document you are reading is about biology will be used when a particular word that has several possible senses (or meanings) is encountered, and the word will be interpreted as having the biology sense.

Of necessity, the following description of levels is presented sequentially. The key point here is that meaning is conveyed by each and every level of language and that because humans have been shown to use all levels of language to gain understanding, the more capable an NLP system is, the more levels of language it will use (Fig. 1).

Phonology

This level deals with the interpretation of speech sounds within and across words. There are, in fact, three types of rules used in phonological analysis: 1) phonetic rules for sounds within words; 2) phonemic rules for variations of pronunciation when words are spoken together; and 3) prosodic rules for fluctuation in stress and intonation across a sentence. In an NLP system that accepts spoken input, the sound waves are analyzed and encoded into a digitized signal for interpretation by various rules or by comparison to the particular language model being used.

Morphology

This level deals with the componential nature of words, which are composed of morphemes (the smallest units of meaning). For example, the word *preregistration* can be morphologically analyzed into three separate morphemes: the prefix *pre*, the root *registra*, and the suffix *tion*. Because the meaning of each morpheme remains the same across words, humans can break down an unknown word into its constituent morphemes to understand its meaning. Similarly, an NLP system can recognize the meaning conveyed by each morpheme to gain and represent meaning. For example, adding the suffix *-ed* to a verb, conveys that the action of the verb took place in the past. This is a key piece of meaning, and in fact, is frequently only evidenced in a text by the use of the *-ed* morpheme.

Lexical

At this level, humans, as well as NLP systems, interpret the meaning of individual words. Several types of processing contribute to word-level understanding (the

Fig. 1 Model of synchronized language processing.

first of these being assignment of a single part of speech tag to each word). In this processing, words that can function as more than one part of speech are assigned the most probable part of speech tag based on the context in which they occur.

In addition, at the lexical level, those words that have only one possible sense or meaning can be replaced by a semantic representation of that meaning. The nature of the representation varies according to the semantic theory used in the NLP system. The following representation of the meaning of the word *launch* is in the form of logical predicates. As can be observed, a single lexical unit is decomposed into its more basic properties. Given that there is a set of semantic primitives used across all words, these simplified lexical representations make it possible to unify meaning across words and to produce complex interpretations, much the same as humans do.

launch(a large boat used for carrying people on rivers,
lakes harbors, etc.)(((CLASS BOAT PROPERTIES
(LARGE)(PURPOSE(PREDICATION
(CLASS CARRY(OBJECT PEOPLE))))))

The lexical level may require a lexicon, and the particular approach taken by an NLP system will determine whether a lexicon will be used, as well as the nature and extent of information that is encoded in the lexicon. Lexicons may be quite simple, with only the words and their part(s) of speech, or may be increasingly complex and contain information on the semantic class of the word, what arguments it takes, and the semantic limitations on these arguments, definitions of the sense(s) in the semantic representation used in the particular system, and even the semantic field in which each sense of a polysemous word is used.

Syntactic

This level focuses on analyzing the words in a sentence to uncover the grammatical structure of the sentence. This requires both a grammar and a parser. The output of this level of processing is a (possibly delinearized) representation of the sentence that reveals the structural dependency relationships between the words. There are various grammars that can be used and that will, in turn, impact the choice of a parser. Not all NLP applications require a full parse of sentences; therefore, the remaining challenges in parsing of prepositional phrase attachment and conjunction scoping no longer stymie those applications for which phrasal and clausal dependencies are sufficient. Syntax conveys meaning in most languages because order and dependency contribute to meaning. For example, the two sentences “The dog chased the cat.” and “The cat chased the dog.” differ only in terms of syntax, yet they convey quite different meanings.

Semantic

This is the level at which most people think meaning is determined; however, as we can see in the above defining of the levels, it is all the levels that contribute to meaning. Semantic processing determines the possible meanings of a sentence by focusing on the interactions among word-level meanings in the sentence. This level of processing can include the semantic disambiguation of words with multiple senses; in an analogous way to how syntactic disambiguation of words that can function as multiple parts of speech is accomplished at the syntactic level. Semantic disambiguation permits one and only one sense of polysemous words to be selected and included in the semantic representation of the sentence. For example, among other meanings, “file” as a noun can mean either a folder for storing papers, or a tool to shape one’s fingernails, or a line of individuals in a queue. If information from the rest of the sentence were required for the disambiguation, the semantic, not the lexical level, would do the disambiguation. A wide range of methods can be implemented to accomplish the disambiguation, some which require information as to the frequency with which each sense occurs in a particular corpus of interest, or in general usage, some which require consideration of the local context, and others which use pragmatic knowledge of the domain of the document.

Discourse

Although syntax and semantics work with sentence-length units, the discourse level of NLP works with units of text longer than a sentence. That is, it does not interpret multisentence texts as just concatenated sentences, each of which can be interpreted singly. Rather, discourse focuses on the properties of the text as a whole that convey meaning by making connections between component sentences. Several types of discourse processing can occur at this level; two of the most common are anaphora resolution and discourse/text structure recognition. Anaphora resolution is the replacing of words such as pronouns, which are semantically vacant, with the appropriate entity to which they refer.^[30] Discourse/text structure recognition determines the functions of sentences in the text, which, in turn, adds to the meaningful representation of the text. For example, newspaper articles can be deconstructed into discourse components such as lead, main story, previous events, evaluation, attributed quotes, and expectation.^[31]

Pragmatic

This level is concerned with the purposeful use of language in situations and uses context over and above the contents of the text for understanding. The goal is to explain how extra meaning is read into texts without actually being encoded in them. This requires much world

knowledge, including the understanding of intentions, plans, and goals. Some NLP applications may use knowledge bases and inferencing modules. For example, the following two sentences require resolution of the anaphoric term “they,” but this resolution requires pragmatic or world knowledge.

The city councilors refused the demonstrators a permit because they feared violence.

The city councilors refused the demonstrators a permit because they advocated revolution.

Summary of Levels

Current NLP systems tend to implement modules to accomplish mainly the lower levels of processing. This is for several reasons. First, the application may not require interpretation at the higher levels. Second, the lower levels have been more thoroughly researched and implemented. Third, the lower levels deal with smaller units of analysis (e.g., morphemes, words, and sentences), which are rule governed versus the higher levels of language processing, which deal with texts and world knowledge, and which are only regularity governed. As is seen in the following section on approaches, the statistical approaches have, to date, been validated on the lower levels of analysis, whereas the symbolic approaches have dealt with all levels, although there are still few working systems that incorporate the higher levels.

APPROACHES TO NATURAL LANGUAGE PROCESSING

Natural language processing approaches fall roughly into four categories: symbolic, statistical, connectionist, and hybrid. Symbolic and statistical approaches have coexisted since the early days of this field. Connectionist NLP work first appeared in the 1960s. For a long time, symbolic approaches dominated the field. In the 1980s, statistical approaches regained popularity as a result of the availability of critical computational resources and the need to deal with broad, real-world contexts. Connectionist approaches also recovered from earlier criticism by demonstrating the utility of neural networks in NLP. This section examines each of these approaches in their foundations, typical techniques, differences in processing and system aspects, and their robustness, flexibility, and suitability for various tasks.

Symbolic Approach

Symbolic approaches perform deep analysis of linguistic phenomena and are based on explicit representation of

facts about language through well-understood knowledge representation schemes and associated algorithms.^[21] In fact, the description of the levels of language analysis in the preceding section is given from a symbolic perspective. The primary source of evidence in symbolic systems comes from rules and lexicons developed by humans.

A good example of symbolic approaches is seen in logic- or rule-based systems. In logic-based systems, the symbolic structure is usually in the form of logic propositions. Manipulations of such structures are defined by inference procedures that are generally truth preserving. Rule-based systems usually consist of a set of rules, an inference engine, and a work space or working memory. Knowledge is represented as facts or rules in the rule base. The inference engine repeatedly selects a rule whose condition is satisfied and executes the rule.

Another example of symbolic approaches is semantic networks. First proposed by Quillian^[10] to model associative memory in psychology, semantic networks represent knowledge through a set of nodes that represent objects or concepts and the labeled links that represent relations between nodes. The pattern of connectivity reflects semantic organization (i.e., highly associated concepts are directly linked, whereas moderately or weakly related concepts are linked through intervening concepts). Semantic networks are widely used to represent structured knowledge and have the most connectionist flavor of the symbolic models.^[32]

Symbolic approaches have been used for a few decades in a variety of research areas and applications such as information extraction, text categorization, ambiguity resolution, and lexical acquisition. Typical techniques include explanation-based learning, rule-based learning, inductive logic programming, decision trees, conceptual clustering, and K nearest neighbor algorithms.^[6,33]

Statistical Approach

Statistical approaches use various mathematical techniques and often use large text corpora to develop approximate generalized models of linguistic phenomena based on actual examples of these phenomena provided by the text corpora without adding significant linguistic or world knowledge. In contrast to symbolic approaches, statistical approaches use observable data as the primary source of evidence.

A frequently used statistical model is the Hidden Markov Model (HMM) inherited from the speech community. The HMM is a finite state automaton that has a set of states with probabilities attached to transitions between states.^[34] Although outputs are visible, states themselves are not directly observable, thus “hidden” from external observations. Each state produces one of the observable outputs with a certain probability.

Statistical approaches have typically been used in tasks such as speech recognition, lexical acquisition, parsing,

part of speech tagging, collocations, statistical machine translation, statistical grammar learning, etc.

Connectionist Approach

Similar to the statistical approaches, connectionist approaches also develop generalized models from examples of linguistic phenomena. What separates connectionism from other statistical methods is that connectionist models combine statistical learning with various theories of representation; thus, the connectionist representations allow transformation, inference, and manipulation of logic formulas.^[33] In addition, in connectionist systems, linguistic models are harder to observe because connectionist architectures are less constrained than statistical ones.^[21,35]

Generally speaking, a connectionist model is a network of interconnected simple processing units with knowledge stored in the weights of the connections between units.^[32] Local interactions among units can result in dynamic global behavior, which, in turn, leads to computation.

Some connectionist models are called localist models, assuming that each unit represents a particular concept. For example, one unit might represent the concept “mammal,” whereas another unit might represent the concept “whale.” Relations between concepts are encoded by the weights of connections between those concepts. Knowledge in such models is spread across the network, and the connectivity between units reflects their structural relationship. Localist models are quite similar to semantic networks, but the links between units are not usually labeled because they are in semantic nets. They perform well at tasks such as word-sense disambiguation, language generation, and limited inference.^[36]

Other connectionist models are called distributed models. Unlike that in localist models, a concept in distributed models is represented as a function of simultaneous activation of multiple units. An individual unit only participates in a concept representation. These models are well suited for natural language processing tasks such as syntactic parsing, limited domain translation tasks, and associative retrieval.

Comparison Among Approaches

From the above section, we have seen that similarities and differences exist between approaches in their assumptions, philosophical foundations, and source of evidence. In addition to that, the similarities and differences can also be reflected in the processes each approach follows, as well as in system aspects, robustness, flexibility, and suitable tasks.

Process

Research using these different approaches follows a general set of steps, namely, data collection, data analysis/

model building, rule/data construction, and application of rules/data in system. The data collection stage is critical to all three approaches although statistical and connectionist approaches typically require much more data than symbolic approaches. In the data analysis/model building stage, symbolic approaches rely on human analysis of the data to form a theory, whereas statistical approaches manually define a statistical model that is an approximate generalization of the collected data. Connectionist approaches build a connectionist model from the data. In the rule/data construction stage, manual efforts are typical for symbolic approaches, and the theory formed in the previous step may evolve when new cases are encountered. In contrast, statistical and connectionist approaches use the statistical or connectionist model as guidance and build rules or data items automatically, usually in relatively large quantity. After building rules or data items, all approaches then automatically apply them to specific tasks in the system. For instance, connectionist approaches may apply the rules to train the weights of links between units.

System Aspects

By system aspects, we mean source of data, theory, or model formed from data analysis, rules, and basis for evaluation.

Data. As mentioned earlier, symbolic approaches use human introspective data, which are usually not directly observable. Statistical and connectionist approaches are built on the basis of machine-observable facets of data, usually from text corpora.

Theory or Model Based on Data Analysis. As the outcome of data analysis, a theory is formed for symbolic approaches whereas a parametric model is formed for statistical approaches, and a connectionist model is formed for connectionist approaches.

Rules. For symbolic approaches, the rule construction stage usually results in rules with detailed criteria of rule application. For statistical approaches, the criteria of rule application are usually at the surface level or underspecified. For connectionist approaches, individual rules typically cannot be recognized.

Basis for Evaluation. Evaluation of symbolic systems is typically based on intuitive judgments of unaffiliated subjects and may use system-internal measures of growth such as the number of new rules. In contrast, the basis for evaluation of statistical and connectionist systems are usually in the form of scores computed from some evaluation function. However, if all approaches are used for the same task, then the results of the task can be evaluated both quantitatively and qualitatively and compared.

Robustness

Symbolic systems may be fragile when presented with unusual or noisy input. To deal with anomalies, they can anticipate them by making the grammar more general to accommodate them. Compared to symbolic systems, statistical systems may be more robust in the face of unexpected input provided that training data is sufficient, which may be difficult to be assured of. Connectionist systems may also be robust and fault tolerant because knowledge in such systems is stored across the network. When presented with noisy input, they degrade gradually.

Flexibility

Because symbolic models are built by human analysis of well-formulated examples, symbolic systems may lack the flexibility to adapt dynamically to experience. In contrast, statistical systems allow broad coverage and may be better able to deal with unrestricted text^[21] for more effective handling of the task at hand. Connectionist systems exhibit flexibility by dynamically acquiring appropriate behavior based on the given input. For example, the weights of a connectionist network can be adapted in real time to improve performance. However, such systems may have difficulty with the representation of structures needed to handle complex conceptual relationships, thus limiting their abilities to handle high-level NLP.^[36]

Suitable Tasks

Symbolic approaches seem to be suited for phenomena that exhibit identifiable linguistic behavior. They can be used to model phenomena at all the various linguistic levels described in earlier sections. Statistical approaches have proven to be effective in modeling language phenomena based on frequent use of language as reflected in text corpora. Linguistic phenomena that are not well understood or do not exhibit clear regularity are candidates for statistical approaches. Similar to statistical approaches, connectionist approaches can also deal with linguistic phenomena that are not well understood. They are useful for low-level NLP tasks that are usually subtasks in a larger problem.

To summarize, symbolic, statistical, and connectionist approaches have exhibited different characteristics; thus, some problems may be better tackled with one approach and other problems by another. In some cases, for some specific tasks, one approach may prove adequate, whereas in other cases, the tasks can get so complex that it might not be possible to choose a single best approach. In addition, as Klavans and Resnik^[6] pointed out, there is no such thing as a “purely statistical” method. Every use of statistics is based on a symbolic model and statistics alone is not adequate for NLP. Toward this end, statistical approaches are not at odds with symbolic approaches. In fact, they are rather complementary. As a result, researchers have begun developing

hybrid techniques that use the strengths of each approach in an attempt to address NLP problems more effectively and in a more flexible manner.

NATURAL LANGUAGE PROCESSING APPLICATIONS

Natural language processing provides both theory and implementations for a range of applications. In fact, any application that uses text is a candidate for NLP. The most frequent applications using NLP include the following:

- Information retrieval. Given the significant presence of text in this application, it is surprising that so few implementations use NLP. Recently, statistical approaches for accomplishing NLP have seen more use, but few systems other than those by Liddy^[37] and Strzalkowski^[38] have developed significant systems based on NLP.
- Information extraction (IE). A more recent application area, IE focuses on the recognition, tagging, and extraction into a structured representation, certain key elements of information (e.g., persons, companies, locations, and organizations) from large collections of text. These extractions can then be used for a range of applications including question-answering, visualization, and data mining.
- Question-answering. In contrast to Information Retrieval, which provides a list of potentially relevant documents in response to a user's query, question-answering provides the user with either just the text of the answer itself or answer-providing passages.
- Summarization. The higher levels of NLP, particularly the discourse level, can empower an implementation that reduces a larger text into a shorter, yet richly constituted abbreviated narrative representation of the original document.
- Machine translation. Perhaps the oldest of all NLP applications, various levels of NLP have been used in MT systems, ranging from the word-based approach to applications that include higher levels of analysis.
- Dialogue systems. Perhaps the omnipresent application of the future, in the systems envisioned by large providers of end-user applications. Dialogue systems, which usually focus on a narrowly defined application (e.g. your refrigerator or home sound system), currently use the phonetic and lexical levels of language. It is believed that use of all the levels of language processing explained above offer the potential for truly habitable dialogue systems.

CONCLUSION

Although NLP is a relatively recent area of research and application, compared with other information technology

approaches, there have been sufficient successes to date that suggest that NLP-based information access technologies will continue to be a major area of research and development in information systems now and far into the future.

ACKNOWLEDGMENT

Grateful appreciation to Xiaoyong Liu who contributed to this entry while she was a Ph.D. student and a Research Assistant in the Center for Natural Language Processing in the School of Information Studies at Syracuse University.

Network Management

Robert J. Sandusky

University Library, University of Illinois at Chicago, Chicago, Illinois, U.S.A.

Abstract

Network management includes activities related to the design, construction, and operation of communications networks, which are performed by a network management organization. Network management is inherently a distributed activity because a network includes equipment distributed across multiple locations. Network management work is described in terms of the five dimensions of network management as defined by the International Standards Organization: fault, configuration, performance, accounting, and security management. Network management work is further described as a melding of design and real-time supervisory control work, depending upon effective information management and coordination of activities within the network management organization and with external organizations, including customers, peer organizations, and equipment and service providers.

INTRODUCTION

Network management includes activities related to the design, construction, and operation of communications networks, which are one type of distributed infrastructure. Network management activities are performed by a network management organization (NMO). An NMO is one of many types of information technology service organizations and, as discussed here, is responsible for the design, monitoring, and evolution of distributed infrastructure (an assemblage of hardware, software, and services) in its particular organizational context. The network itself is the primary object of the NMO's work and the NMO generally has little influence over how the network is used by other members and affiliates of the organization. An NMO may be a single organization but will typically interact with multiple organizations including customers, peer organizations collaborating to provide network services, and vendors. Network management, in all but the simplest cases such as a home or small single-site local area network (LAN), is inherently a distributed activity: a network usually includes equipment distributed in multiple locations. At the smaller end of the scale, equipment may be located in multiple rooms or on multiple floors of a building (referred to as a LAN). In more complex cases, the equipment may be located in multiple buildings (on a campus or across a metropolitan area, often referred to as a MAN, or metropolitan area network), in multiple cities, or even multiple countries (a WAN, or wide area network). This entry will assume, for purposes of illustration and discussion, a MAN or WAN unless otherwise noted.

This entry begins with a brief description of the types of components that make up a MAN or WAN and are the network components that require management. The five major dimensions of network management, as defined by

the International Standards Organization (ISO) as part of the Open Systems Interconnection model, are used to introduce the range of activities associated with management of complex networks. Next, how design work is approached in NMOs is discussed in terms of the classic "waterfall" software development life cycle. The dynamic and collaborative nature of work within an NMO is described in terms of two interrelated modes of working: design work and real-time supervisory control work. Finally, the critical role of information management is described in the context of a disaster recovery/business continuity test.

WHAT IS MANAGED IN A NETWORK?

Networks, including the Internet, closed or private networks built by organizations, and smaller-scale LANs, are composed of several classes of components. Applications (e.g., Web sites, enterprise databases, digital libraries, e-mail systems) made accessible to remote users, messages carried by the network (i.e., frames, packets), end-user computers (i.e., client computers), server computers (e.g., Web servers, file servers, proxy servers), routers, switches, hubs, equipment racks, link signaling devices (i.e., link encryptors, digital signaling units/digital "modems"), access lines (e.g., the Ethernet cabling from client computers to a local switch, router, or hub), wireless access points, and long-distance telecommunications circuits (e.g., the higher-capacity, leased digital line between network locations usually connecting routers to each other).^[1] All of these network components, except the cables, contain software and configurable parameters and all must be managed in order to provide effective network services that evolve to meet demand and keep pace with technical

innovations. Vendor-provided software for configurable components must be tested and implemented to fix bugs, patch security holes, and to add functionality. The NMO also monitors the network in real-time for failures, errors, traffic bottlenecks, etc., and corrects problems by issuing commands to change component state and by swapping failed components with replacements. The NMO also monitors actual usage patterns and takes requests for new services into account as part of its network design and provisioning work.

The NMO must have the means to organize information about all the elements of the network in order to manage these components. The NMO must also have a set of operating parameters that, in combination with the network components, can enable the NMO to create appropriate standard operating procedures (SOPs) and ancillary support systems such as trouble ticket, configuration management, test scheduling, and reporting systems.

DIMENSIONS OF NETWORK MANAGEMENT

A conceptual framework associated with the ISO's Open Systems Interconnection model for communications systems is used to organize the full range of network management activities.^[2] While originally focused on network management, this framework may be used to characterize the management of distributed computing systems more generally. The OSI framework is broken down into five functional areas: fault management, configuration management, performance management, accounting management, and security management.

Fault management is the detection, diagnosis, and correction of problems, or faults, in a network. Network components asynchronously generate fault data as messages, referred to as alarms, which are categorized as major, minor, and informational depending upon their significance or impact. Major alarms are generated when a network component fails due to hardware failure, software failure, or because the component can no longer be contacted by the network management systems (i.e., it has become isolated from the rest of the network). Minor alarms are generated when less critical events are detected, such as a performance threshold being exceeded, a burst of transmission errors is detected, or a failure of a subcomponent (e.g., a single interface card failure on a large router). Informational messages are generated for a variety of reasons, do not require direct attention by the real-time supervisory control (RTSC) staff, but are logged and available if needed (e.g., an anomalous but automatically recoverable condition, such as a communications protocol error). As alarms are generated, they are propagated to the NMO via both a real-time and an archival path. Alarms are sent to network management workstations that are continuously monitored by RTSC staff and to databases for long-term alarm storage. Propagation of

alarms to the network management workstations supports the real-time work of isolating and correcting faults requiring direct intervention by NMO staff. Examples of faults requiring real-time intervention include failures that do not automatically recover or large-scale failures that trigger the performance of a SOP. Propagation of alarms to databases provides comprehensive historical data for postevent, trend, or long-term fault analysis. Faults are logged in a database using a record format that includes date, time, location, fault codes, and other information of potential use in diagnosis, correction, or to support subsequent, long-term analysis. To support fault diagnosis, NMO staff use diagnostic test tools and component status query commands to retrieve real-time component status, and various component activation/deactivation commands to alter component status or component operating parameters. NMO staff are trained in troubleshooting procedures, and have access to SOPs for monitoring the network, documenting fault conditions in trouble tickets, and problem escalation (i.e., when to contact next-level expertise and/or management if a fault cannot be corrected in a timely manner). Trouble tickets are created for all faults requiring intervention. The trouble ticket is a locus for a textual narrative of the situation as it unfolds, providing capabilities to combine descriptions of evidence, activity, causal hypotheses, as well as a record of interpersonal, intra-, and inter-organizational communications. To correct faults that have been diagnosed, the NMO staff use commands to alter physical configurations (e.g., to replace a failed component with a backup component), manually activate a deactivated component, or to modify the operating parameters of affected components.

Configuration management is the set of capabilities that allow the NMO to set up and modify the network's physical and logical configurations. Following initial implementation the network's physical and logical configurations will change "to alleviate congestion, isolate faults or meet changing user needs."^[2] Configuration changes may be unplanned, caused by network faults, or as a result of NMO staff action in response to a fault or changing, real-time network conditions, or as part of a preplanned configuration change. Faults often cause spontaneous network reconfigurations, such as removal of a long-distance telecommunications link from the network topology. Networks must be fault-tolerant: their internal complexity (the large number of varied and interconnected components) and reliance on long-distance telecommunications links result in frequent (e.g., several per day) single component failures. Therefore, networks must be designed to tolerate all single-component failures in order to be considered minimally reliable. In order to provide availability on the order of 99.9% or higher, the design must tolerate the simultaneous failure of any two components. In some situations, networks are designed to tolerate all dual-component failures as well as a subset of three-component failures. Network components are designed to attempt

automatic recovery following failures, and many failures are corrected automatically. In a significant percentage of cases, NMO diagnosis and correction are required to either effect component recovery (e.g., manually reactivating a component) or to temporarily reconfigure the network so connections and traffic flow around the failure (e.g., moving a LAN's connection from its failed default router to an available connection on an alternate router). Planned network reconfigurations take two forms: predesigned modifications that are intended to be permanent, such as changes made to address new requirements, and predesigned modifications that are intended to be temporary, such as those that are part of disaster recovery/business continuity plans. Adding, modifying, or removing routers, interface cards to a router, or telecommunications circuits between routers are examples of common planned permanent configuration management activities. Network planning and design work is required prior to implementation of either a new network or a significant revision to an existing network. One of the implications of designing a fault-tolerant system is the need to preplan the organization's responses to a range of anticipated fault events including normal, single-component failures (e.g., loss of a long-distance telecommunications link) or high-impact failures (e.g., complete loss of connectivity for a network site, whether it is caused by natural disaster, massive telecommunications link failure, fire, simultaneous failure of both primary and backup routers, etc.). Preplanning work is complex, and results in the creation of SOPs that guides NMO reconfigurations in response to classes of failures (see discussion below in the section on "Perspectives on Network Management Work").

Performance management refers both to the capabilities in the network that support measurement of network use and the expertise within the NMO to analyze data, justify recommendations for change, and plan the configuration changes needed to support emerging or anticipated network uses. NMOs are interested in understanding and documenting past usage patterns, comparing current usage patterns to historical patterns, and using both historical and current data to support the capacity planning process. While performance monitoring occurs in real-time as the RTSC staff continuously monitor utilization of network components like routers and long-distance telecommunications links, the bulk of performance management activities are performed "off-line" by design staff. Network components periodically—every few minutes—log levels of usage by writing data to network management servers for later analysis. Network components may also generate fault messages or alarms when utilization levels exceed certain thresholds to enable real-time supervisory staff to respond with network configuration changes. Networks and their protocols are designed to be tolerant of fluctuations in network traffic or topology, so real-time intervention is not usually required. Performance management is part of the longer-term network design process and involves analysis

of the logged performance data in order to detect changes in usage patterns that lead to modifications in the network's configuration. For example, increasing network traffic between two locations may lead to installation of higher capacity routers, telecommunications links, reconfiguration of the network topology, or a combination of the three.

Accounting management is the set of capabilities that allows the NMO to collect and manage usage and configuration data, track costs, and charge network users according to the tariffs, service level agreements, or contracts that are in place. Several network components may be capable of generating and transmitting usage data that may be fed into an off-line accounting or billing system (e.g., routers and servers running shared applications may generate data that are fed into a billing system). Costs of other components, such as cables, routers, or equipment racks, may have their costs allocated on some other basis (such as employee head count or a count of connections), or may be factored into usage-sensitive charges. NMOs evaluate the costs, benefits, and complexity of collecting and correlating large amounts of data and negotiating customer agreements in order to produce detailed bills against other approaches that don't require detailed usage-based calculations (e.g., simpler, flat-rate or percentage-allocated cost-recovery arrangements). The simpler approaches are particularly useful for networks built to support the internal operations of an organization. NMOs providing services to the public, such as land-line and mobile telecommunications organizations, are more likely to develop usage-sensitive procedures.

Security management is concerned with control of physical access to network components, end-point authentication, user authentication, key management for encryption, end-to-end data encryption, security log management, monitoring emerging security threat vectors and developing organizational responses, and firewall management. Security management has two objects in the network management context: first, the network itself must be secured (e.g., control the access to router management ports which are used to issue reconfiguration commands to the router; ensure that physical access to network equipment at all locations is controlled; manage NMO staff authentication and access); second, the network must support the security requirements of the users and applications transmitting data across the network (e.g., providing encryption of telecommunications circuits; end-to-end encryption of data streams; management of encryption keys). In environments with high security needs, including financial institutions, health care organizations, and commercial organizations in highly competitive markets, security management responsibilities are concentrated in an independent part of the organization, with a management chain distinct from the RTSC and technical staffs. A separate management chain encourages, enforces, and makes a high degree of transparency possible through establishment of arms-length relationships between different parts of the NMO. NMOs with these types of stringent needs

will also employ a comprehensive internal auditing process, augmented by recurring external audits. Security logs, like fault logs, identify date, time, location, and diagnostic information. Security logs should be reviewed regularly in order to identify unusual usage patterns or to correlate successful and unsuccessful access attempts by users and intruders alike. Several of the activities included in security management, including encryption key management and developing responses to emerging security threats, are complex management challenges in a distributed environment (see the entry “Authentication and Authorization,” p. 413).

PERSPECTIVES ON NETWORK MANAGEMENT WORK

Network management depends upon the blending of actions performed by people with a range of skills and expertise, and these actions depend upon information management practices. Design and RTSC work patterns are defined, and the central role of information management in network management is described. These two work patterns are discussed in the context of the five dimensions of network management. The section concludes with a description of a complex yet typical activity, a disaster recovery test (DRT), which illustrates the relationship between information and activity in distributed infrastructure management.

Patterns of Work

Network management combines patterns of both design and RTSC work. Research has shown that design work and RTSC work have different rhythms and patterns that, in network management, are coordinated to perform fault, configuration, performance, accounting, and security management. RTSC work is event driven, dynamic, and involves the interaction of multiple workers with complex systems.^[3] Malfunctions in the operation of these systems can result in serious consequences such as the loss of human life or financial loss. Signs of malfunction must often be recognized and responses formulated within minutes or seconds in order to prevent adverse consequences. By contrast, design work has different patterns and rhythms than RTSC work and is characterized as being self-paced (as opposed to being event-driven), reflective (as opposed to being time-constrained), and creative.^[3–5] The object of design work is usually to iteratively create, study, or revise some artifact like a document, a set of specifications, a product, or a system, such as a data communications network. In network management, there are frequently occasions when workers who usually do design work join the RTSC staff to perform event-driven and time-constrained work, particularly with regard to fault and configuration management. This section will first describe how an NMO for a WAN is organized. How new network implementations are managed is described next, followed

by a description of the role of information management in network management work. Finally, the five dimensions of network management (above) are discussed in terms of design work and RTSC work.

The NMO for a large network, such as a national-scale WAN, includes a staff of technical specialists who provide depth of knowledge in particular technologies, the RTSC staff, budget, accounting, and administrative support staff, and executive management. Categories of technical specialists include network hardware engineers, network software engineers, data security specialists, and circuit/topology experts. Network hardware engineers are specialists in network equipment, signaling equipment, electrical requirements, lower-level network protocols, and troubleshooting. The most skilled network hardware engineers will have degrees in computer or electrical engineering. Network software engineers are more likely to be trained in computer science, and will have expertise in higher level network protocols, software debugging, software development, and software engineering processes (e.g., the waterfall systems development life cycle discussed below). Circuit/topology experts manage the leased long-distance telecommunications circuits and the relationships with the vendor or vendors from whom they are leased, and are responsible for managing the network topology. Security specialists may have backgrounds in either engineering or computer science, but will focus on authentication, authorization, dedicated security hardware (e.g., link encryptors and firewalls) and encryption key management processes. In large NMOs, the security experts will be in a separate group and report to a different manager than do the hardware and software engineers in order to maintain arms-length relationships and help ensure that security procedures and standards are not compromised by expediency (e.g., cost or schedule pressures). In total, these technical experts are referred to here as “members of the technical staff.”

The RTSC staff is organized into three shifts, with shift supervisors who report to the supervisory control manager. The RTSC staff are the people who work most directly and most often with the network itself, monitoring the network’s health and configuration (fault and configuration management). The RTSC staff also act as the human interface between the network and the NMO’s internal and external customers. The RTSC staff work in one or more centralized network control rooms. RTSC staff backgrounds are likely to vary from some who have university degrees in a variety of technical and nontechnical fields, to those who have experience in real-time operations but little or no postsecondary education.

The budget and accounting staff rely upon information generated by and about the network to manage billing, budgeting, and financial planning. The executive managers often have backgrounds that include a degree in a technical field and experience as a member of the technical staff. As managers, they will have a well-developed model of the technology and the ability to perform

cross-community coordination with the various NMO groups (members of the technical staff, RTSC staff, accountants), internal and external customers, and vendors.

Network design and software engineering processes have many parallels, and can be described by well-known life cycle models such as the “waterfall” model of software development (Fig. 1). In both situations, the goal is to create a new object: the network or piece of software. The life cycle begins with the identification and documentation of *requirements*. Given a set of relatively stable requirements, one or more *design* alternatives can be produced to satisfy the requirements. Given agreement on a design, *implementation* of the object can begin. As the object is created, each discrete piece undergoes *testing*, and the object is ultimately tested as a whole. After successful testing, the object is released and goes into *maintenance* (software) or goes into *production operation* (network). The life cycle is repeated as new requirements emerge. Each of these subsequent iterations can be managed using the same life cycle model: new requirements are documented, a network design revision is created, and the changes are implemented, tested, and made operational. The NMO is responsible for managing the entire implementation/revision life cycle for its network, and the cycle can be reiterated many times throughout the useful life of the network. Typical types of new requirements for a network include expanding the network into new locations, increasing capacity, or adding support for new data transmission protocols.

In order to design a new network (or modify an existing network), requirements must be gathered to inform the network design (network locations, traffic patterns and types, security and reliability requirements, service level requirements, cost parameters, etc.). During the network design process, engineers use a combination of formal, algorithmic, and professional heuristic processes. For example, given a certain expected traffic load, algorithmic tools can be used to define the number, arrangement, and sizes of routers and the circuits connecting them. The arrangement of routers and circuits is referred to as the

Fig. 1 The “waterfall” systems development life cycle.

Fig. 2 Full mesh topology, where A, B, C, D, E, and F are network sites.

network topology. WANs are never designed as a completely interconnected mesh (i.e., each site linked directly to each other site, Fig. 2), so the topology must be carefully designed to provide adequate support for the traffic patterns and service-level expectations while minimizing operating costs: long-distance circuits between cities are often leased from a telecommunications provider and have recurring monthly costs (Fig. 3). The set of equipment and services needed can then be acquired, installed, and tested. Any moderately complex network is, when built, an ecosystem comprised of a wide variety of equipment and services, including cables, equipment racks, signaling devices (e.g., encryptors and digital “modems”), routers, and network management servers and workstations. Each type of equipment (e.g., routers) can be thought of as a species within the ecosystem. Engineers plan and manage installation and testing of hardware and services at each site (the routers, link signaling

Fig. 3 Optimized network topology, where A, B, C, D, E, and F are network sites.

devices, switches, hubs, racks, long-distance telecommunications circuits, wired and wireless access points, and cables). Software engineers define and test connection parameters and system options within routers, link signaling devices, and any other software-configurable network components. RTSC staff monitor and control the systems as they are installed and tested, perform routine tasks (on both a daily and per-shift basis) and respond to faults. Documentation, policies, and SOPs are developed and refined throughout the planning, implementation, and testing phases. Customer endpoints (LANs, hosts, servers, and applications) are connected to the network, tested, and the new network is in production operation and maintenance mode. Following initial implementation of a network, configuration change tends to be gradual, to replace failed equipment, replace a species (e.g., routers) with an upgraded version, or to make modifications in response to changing user or organization needs. Whether initial installation or incremental upgrade, network reconfigurations include both physical changes (replacing a hardware component), software changes (modifying software parameters related to the component, also known as provisioning), and changes to the documentation.^[6]

Management of distributed infrastructure, including network management, is information-intensive work. Each kind of equipment included in the network is managed by its own workstation-based suite of applications tailored to manage that layer of technology. Each of these systems contains a database (the Management Information Base, or MIB) that provides a representation of the configuration of that layer of the network, providing an accurate, one-to-one correspondence to the physical network configuration. Information in each MIB is, however, isolated and few tools exist to provide effectively merged views of data from all layers of the network. SOPs are created, using an iterative process of proposal, negotiation, and testing, in order to define preplanned and vetted operational sequences for use in routine and nonroutine but anticipated situations. SOPs are organization and context specific, reflecting organizational values and priorities as well as the combinations of technology that make each WAN unique (e.g., kinds of equipment and locations). Some (SOPs) are so commonly used that the RTSC staff has them memorized and the paper documents are only used by newcomers or as referents during discussion. Other procedures, like disaster recovery procedures, are hopefully never actually used. Versions of these types of procedures are often modified into test scripts, which are used once and then discarded.

The NMO staff creates formal databases and other information management tools to serve the specific needs of the NMO, such as trouble ticket, configuration management, and test scheduling systems. Other formal information systems include the vendor provided MIBs and the NMO's own SOPs. Other more situated and less formal information systems included are handwritten notes and

collections of information assembled by individuals, created spontaneously by the NMO staff in order to allow them to do their work more effectively. The informal systems often combine information drawn from one or more formal information sources. The combination of information from multiple sources results in new information compounds^[7] that highlight, through processes of extraction, juxtaposition, and integration of domain semantics, what is salient in a domain rich with information.^[8] People from all parts of the organization spend a great deal of time seeking and gathering bits of formal data, adding the organization-specific stuff of meaning and context, and producing useful, but often difficult to find and manage collections of information. These informal information compounds are often expressed in tabular format in order to represent relationships between physical and logical objects. The relationships of logical objects (like the symbolic or mnemonic name of a network device) to physical objects (like a port on a router or a cable) are enormously important during troubleshooting or in planning for network changes. These information compounds are a means by which the members of the NMO can introduce the organization-specific data about customers, purpose, and meaning into both the real-time supervisory control and design environments. However, maintaining the integrity of these informal representations over time is difficult due to the high rate at which changes are made to the network configuration.

Schematic drawings of relationships between network devices are another common information compound useful in highlighting important relationships between discrete elements in the network. These, too, are prone to problems caused by change and poor document maintenance.

Patterns of Work and Dimensions of Network Management

The degree to which members of the technical staff, who are primarily responsible for network design work, and the RTSC staff, who are responsible for monitoring and controlling the network in real-time, share and coordinate the work associated with the five dimensions of network management varies by dimension, and is influenced by the values, priorities, and other characteristics of the NMO. The work patterns described below are based upon network management work as practiced in a large financial institution,^[9] but are typical of any NMO operating a WAN in a context where high security, reliability, and availability are expected.

In terms of fault management, members of the technical staff will be engaged in the requirements definition and implementation of equipment and software related to fault management. Software engineers may develop or customize systems for managing alarm data in either real-time or for fault diagnosis or post hoc fault analysis. Members of

the technical staff do not participate routinely in fault monitoring activities: this is the responsibility of the RTSC staff. However, under certain conditions, such as during real-time troubleshooting, members of the technical staff merge with the RTSC staff—usually joining together in the network control room—to isolate and resolve a difficult problem as quickly as possible.

Faults requiring intervention occur frequently in large networks, often because of the complex hardware and software configurations located at each network site or because of problems with the telecommunications circuits that connect network locations to each other. An NMO creates procedures (SOPs) that define the canonical responses to typical fault situations. RTSC staff use the SOP as a reference when responding to typical faults, which should result in rapid service recovery performed in a standardized manner. If the standard response does not work, the RTSC staff moves into troubleshooting mode in order to restore service to affected users (by perhaps reconfiguring the network so that redundant or alternate components can be used by the affected users), isolate and characterize the outage, document the outage in a database (by creating a trouble ticket that serves as a collection point for alarms, actions taken, actors involved; a trouble ticket created in response to nonroutine events becomes a narrative of the NMOs collective actions), and escalate the situation (i.e., notify management and next-level technical support, including hardware and software engineers who are responsible for network design and are typically expert in relatively narrow areas such as circuits, routers, or security; or possibly equipment or service providers).

Configuration management is primarily performed by members of the technical staff using a reflective, self-paced, and creative design process, although the RTSC staff are involved for the implementation, testing, and ongoing maintenance. A standard implementation process, such as the waterfall process described above, is typically used to manage preplanned, permanent configuration changes. The RTSC staff may make temporary configuration changes in response to network faults, or as part of the execution of a SOP (e.g., see the description of a DRT, below).

Performance management is almost entirely done by members of the technical staff in a reflective process where data collected by the network is compiled and analyzed. In rare cases, real-time network congestion may bring RTSC and design staff together in the control room for real-time analysis and intervention. These rare real-time situations are likely to cause a network capacity review by members of the technical staff.

Accounting management is also almost entirely a post hoc, off-line activity. RTSC have little to do other than ensure that the accounting data is being collected continuously. Accounting data is usually important to the NMO even in cases where detailed usage tracking is not done; usage information is still likely to be used to demonstrate

NMO and network relevance as well as to help apportion network costs to customer organizations.

Security management involves members of the technical staff most directly and includes managing access control, user accounts and passwords, and encryption key management procedures. The RTSC staff does get involved, particularly in diagnosing suspected link encryption or data encryption problems. In a 24 hour, high-security environment, additional control procedures are required to manage access to “superuser” passwords that may need to be accessed from a secure location, such as a safe, when required for fault resolution.

Information and Activity in Network Management

An example of how an NMO plans and conducts a disaster recovery, or business continuity, test (DRT) is indicative of the ways the design and RTSC staffs interact and of the reliance of the NMO on effective information management. The DRTs in a WAN are complex. The DRT scenario assumes that the entire network site, its servers, and LANs at that the site have all been disabled (e.g., due to a fire, flood, etc.). A private network with high standards for availability would set as a network design requirement the ability to survive the complete loss of any network site by providing connectivity at an alternate, backup site. This requirement directs many other decisions and activities. For example, the need to redirect huge flows of data from a failed site to a backup site has an impact on the initial design of the network and its topology, as well as the way recovery mechanisms within the network are customized. The NMO also commits significant human resources from the technical and RTSC staff to create SOPs that will support this sort of recovery within the target times, which require complete network and server recovery within a few hours of the outage. The SOP likely contains scores of steps that are to be performed in a preplanned sequence, often by multiple organizations working in coordination. Such a complex document must be created and reviewed by both RTSC and technical staffs: the members of the technical staff are subject matter experts with deep knowledge of a narrow technical specialty, while the RTSC staff have broad working knowledge of the range of network technologies, but with less technical depth. The RTSC staff’s “big picture” view of the network and the organizational environment allows them to contribute information about how activities should be sequenced and coordinated, both within and across the participating sites. People from multiple organizations and sites must be familiar with the procedures and rehearse them regularly. Backup data must be transmitted regularly, often on a continuous transaction-by-transaction basis, or by using daily data transfers. In either case, these data transfers become part of the RTSC staff’s ongoing responsibilities.

The planning for a DRT begins a couple of months before the test date. A DRT director, usually a manager, is assigned responsibility for planning and running the test. Draft test scripts are distributed, which are modified versions of the SOP. The modifications reflect the goals and exceptions for the current test. (It is, as a practical matter, nearly impossible to take a major site out of the network for the 18–24 hours it takes to run a disaster simulation and test all of the recovery and fallback procedures. The tests are invariably limited to some degree to accommodate other competing requirements.) Conference calls are held where the site being tested, the NMO, and any other sites involved in recovery of servers “walk through” the script, looking for errors, sequencing problems, negotiating modifications, and inserting proper articulation and control points (e.g., periodic management conferences to review progress and status when the test is executed). Members of the technical staff and RTSC staff are present at all of the planning meetings and participate in the discussions and negotiations. The SOP is designed to serve as a canonical text in that it embodies the actions to be taken in the event that an “ideal” disaster occurs: a complete, total disaster at the site that would render it unusable. As such, the SOP embodies a “best practice” approach to dealing with a disaster, providing guidance on the most reliable way to effect the recovery of each piece of the failed environment at the backup sites. At the start of the test, the disaster itself is simulated, and how the simulation is to be performed is part of the test script. Specific dates and times are included in the test script to provide a rough sense of what it means to be on or behind or ahead of schedule during the test, values which are not included in the canonical SOP.

As the test date nears, it is discussed during the normal change and scheduling meetings to ensure the readiness of the NMO and other direct participants, to allow new information to be integrated into the schedule and plan, and to ensure awareness by a wider range of people and organizations who may be conducting other activities that overlap with the DRT. The day before the test begins, a final meeting is held, attended by representatives from all locations with responsibility for conducting the DRT. This meeting is the last opportunity for cancellations, late modifications to the test script, discussion of resource conflicts, times, etc.

The DRT begins a couple of hours before dawn, and RTSC staff from the NMO are responsible for many of the first steps to reconfigure the network to support movement of servers and other systems from the site under test to various recovery sites at other locations across the network. The third shift NMO staff cannot participate in daytime planning meetings that have occurred during the past week, and so they rely upon the written test schedules and scripts, plus any information passed verbally to them by the previous shift staff. They are also likely to have other network reconfigurations to perform during the

same time period, near the end of their shift. If this part of the day goes well, the NMO will be in good shape for the entire weekend. If not, the political fallout could last for weeks. The site disaster will be simulated by disabling all of the network connections from other network sites to the site under test, in effect isolating that site from the rest of the network. The NMO RTSC staff issue status commands to ensure that the circuits are inactive. Alarms printers and displays record the disables as well as hundreds of other, cascading events. Network elements, represented by icons, change from green to red on many of the workstations. The NMO RTSC staff contact the test director to report that their current task is completed.

Contingencies are bound to arise in any event this complex. One site may get a late start; there may be problems reading a tape when trying to restore a software image at the backup site. The NMO is also likely to be dealing with normal problems, such as circuit problems that are causing high error rates and affecting network performance. In real time, processes move forward at the many participating sites. Some parts of the process get stuck and require intervention; some succeed; others simply fail, and the test script is modified on the fly in a continuous series of phone calls and negotiations. When the reality of the test day proves problematic, people can refer to the plan and make on-the-spot decisions about how to work around the difficulty: steps may be done in the “wrong” order, certain steps skipped, or certain steps repeated. These variations must be noted at the NMO as they occur, both to keep track of the test status in real time and as information to be used to modify the underlying SOP and subsequent similar test scripts.

The duration the DRT and other tests may span shift boundaries, making it necessary for accurate status to be passed from shift to shift. Managers from the NMO need status and may be on site or at home. The technical staff members supporting this and other simultaneous tests need to be aware of the status of the major test and adjust their weekend activities accordingly. The NMO must coordinate its activities through the DRT manager. As the test runs, problems may occur which must be resolved. Some parts of the test may be omitted in response to unexpected problems to avoid compromising the entire test.

The final event associated with a DRT is the postmortem held the following week. The participants in the postmortem are the same as those who participated in the many pretest meetings. The DRT director in effect grades the performance of the participants. The NMO and other organizations are held responsible for problems arising during the test. Responsibility for resolving each problem is publicly assigned. Resolution of problems assigned to the NMO may involve modifying the SOP or making configuration changes to the network. Even though problems occur during the DRTs, they are, due to the careful preplanning and test-day coordination, almost always considered successful.

CONCLUSION

Network management is not exclusively a technical issue of routers, telecommunications links, servers, applications, and the interconnections of LANs via metropolitan or WANs. Effective network management depends upon the blending of design and RTSC work to support all dimensions of network management: fault, configuration, performance, accounting, and security management. Effective organization and control of complex, dynamic information is also important to the NMO, as it enables the recording and communication of large amounts of information in forms that incorporate the values of the NMO and the larger organization within which it is embedded. While the five dimensions of network management form a common basis for organizing network management across a wide variety of organizations, the details of network management practice are situated and influenced by security requirements, available technical expertise, and budget. The concerns of network management apply as well to other situations in which distributed infrastructure must be managed.

Standards published by the Internet Engineering Task Force (IETF) have come to dominate network management practice. The most important of these are the Simple Network Management Protocol Version 3 (SNMPv3), defined in Requests for Comment 2571–2575.^[10–14] Further information about the technical aspects and best practices of network and infrastructure management, including how SNMPv3 is used in practice, can be found in a number of works, including Limoncelli–Muller.^[15–18]

Network of European Museum Organisations (NEMO)

Frank Birkebæk

Roskilde Museum, Roskilde, Denmark

Abstract

European professional museum organizations joined together in 1992 in order to establish a political network of museums that would be able to act on a supranational level within the EU.

The Network of European Museum Organisations (NEMO) was founded in 1992, based on a Danish initiative. The intention was to establish a cooperation between the museum organisations within the then EC. Besides Denmark, Great Britain and Holland were the other driving forces in furthering this work.

The Maastricht Treaty made the need for NEMO even more evident and gave the network a clearer political dimension. After Maastricht, museums had to be able to act on a supranational level.

NEMO is an initiative for professional museums organizations, but professionally staffed state institutions and committees are invited to join from other countries, where no nationwide organisations exist. NEMO is set up with minimum bureaucracy. It is informally structured and has led to a flexible and workable organisation.

NEMO's members meet for 2–3 days every year. The meetings are held in rotation in the member countries, and are led by the chairman and the executive committee, who together monitor the work in NEMO and prepare for the annual meeting. The secretariat follows the chairman.

NEMO tries to get the expenses for running the secretariat and network financed by EU programs. The executive committee meets 2–3 times a year. One of these meetings is held at Brussels, and includes meetings with other cultural networks, with the cultural committee

of the Parliament, and with the relevant offices of the Commission.

NEMO has made the presence of museums felt in the EU, and it is the duty of NEMO to bring museums into the current political debate. NEMO does so, by means of its meetings and contacts at Brussels, by taking part in conferences, by cooperating with other networks, by the distribution of information on the work and necessity of museums, by written submissions, and, especially, by contributing to different EU programs. The latest example is the compilation of a standard loan agreement for museums, which will make it easier to procure mobility of collections within Europe.

NEMO has brought about a close cooperation between museum organisations within the EU, and gaining knowledge and understanding each other has been one of the most important results of NEMO's activities. NEMO has also been part of the inspiration behind a new attempt to create a global collaboration among professional museum associations.

NEMO's Web site is a meeting point for museums that are looking for partners for projects. NEMO's Web site is also the forum for dissemination of information from EU that is relevant for museums.

Today, NEMO is considering its role in the future. Will it be obliged to be formal in order to meet the demands of formality from EU authorities? Or can it stay informal and keep the flexibility of an independent network?

Networked Knowledge Organization Systems/Services (NKOS)

Marianne Lykke

Information Interaction and Architecture, Royal School of Library and Information Science,
Aalborg, Denmark

Abstract

The NKOS Community is described in this entry. NKOS (<http://nkos.slis.kent.edu/>) is an informal network of academics and practitioners who are interested in the use of knowledge organization systems (KOS) in networked information environments. The general aim of the community is to enable KOS to act as networked information services (both machine-to-machine and human-computer), and support the description and retrieval of information resources on the Internet. The community is a forum for presentation and discussion of KOS applications, and interchange of ideas, from technical issues to intellectual, semantic, and terminological problems related to the use of KOS. The participants come from a variety of disciplines, and from academia as well as practice, and interact and communicate by a diverse set of means: annual workshops in the United States and Europe, a Web site, a mailing list, and publication of special journal issues and working papers about contemporary issues. The NKOS community represents topical diversity, informality, and multiple perspectives on networked KOS applications. There is an implicit danger that this variety diverts the focus and discussion. However, it appears from the analysis that the constancy in the organization of the activities and the well-established peer review process is adequate to attract participants, maintain satisfactory quality, and keep focus in multiplicity.

INTRODUCTION

Networked Knowledge Organization Systems/Services (NKOS) is an informal network of academics and practitioners from a variety of disciplines who are interested in the use of knowledge organization systems (KOS) in networked information environments. The notion of KOS covers a wide range of systems from authority files, classification systems, thesauri, gazetteers, and ontologies.

The NKOS network interacts and communicates by a diverse set of means. Since 1997, there has been an NKOS workshop each year, at either the Joint Conference on Digital Libraries (JCDL) or the European Conference on Digital Libraries (ECDL). In addition, NKOS Special Sessions have been held occasionally at other conferences or seminars. NKOS-related special issues have appeared in the online Journal of Digital Information (JoDI) in 2001 and 2004 and in the printed journal *New Review of Hypermedia and Multimedia* (NRHM) in 2006. A variety of KOS-related documents have been proposed and emerged from the NKOS community.

The community operates a mailing list, <http://listserv.oclc.org/archives/nkos-l.html>, today hosted at the Online Computer Library Center (OCLC). Diane Vizine-Goetz, OCLC oversees the list. From June 2001 to May 2007 the archive of the NKOS mailing list was hosted by the National Science Foundation (NSF) DLI2.^[1] There is access to information about activities and means of communication at the NKOS Web site (<http://nkos.slis.kent.edu/>), hosted and administered by Marcia Zeng, Kent State University.

This entry is a description of the NKOS community, its interests, and activities. The remainder of the entry is organized as follows. Section “Aims, Participants, and Topical Focus” provides an overview and discussion of the aims, participants, topical focus, and themes that NKOS covers. Section “The NKOS Workshops and Special Sessions” presents the NKOS workshops and other NKOS meetings. Section “Special Journals Issues” discusses the special journal issues and other related documents proposed and developed within the NKOS community. Section “Conclusion” sums up and concludes about the contribution of NKOS.

AIMS, PARTICIPANTS, AND TOPICAL FOCUS

NKOS is devoted to the discussion of the functional and data model for enabling KOS as networked interactive information services to support the description and retrieval of diverse information resources through the Internet.^[1]

From the start the NKOS community and its primary means of communication, the NKOS workshops were planned to be an *informal* meeting place for researchers and developers, a forum for discussions and interchange of ideas and experiences. In calls participants are encouraged strongly to present problems or lessons learned that will benefit from workshop discussion. Substantial, extensive discussions, with “crosscutting discussion points,” is a crucial goal for the NKOS workshops.^[2] At every the

workshop a portion of the meeting time is reserved for informing about research and development projects, current as well as planned, deliberately with the idea of exchanging ideas and identifying collaborative development opportunities.

The workshops invite participants internationally from the industry as well as academia, and looking at the workshop programs participants also embrace a wide range of disciplines and professionals: thesaurus, taxonomy and ontology developers, digital library and information infrastructure developers, library, museum and archive professionals, standard developers, user interface designers, and knowledge managers. The workshops bring together developers of traditional KOS tools such as classification schemes and thesauri and developers of newer semantic tools such as ontologies and topic maps, and as such provide a meeting room where recent KOS development can take advantage of the vast body of knowledge from more traditional systems and where the practices for traditional KOS structures can benefit from the technological advances being developed to improve semantic access to Web content.

The main, overall workshop topics are themes related to KOS applications and networked implementation of KOS, ranging from technical challenges, terminology and standards development, identification of user needs, and understanding of the advantages and the general scenario for searching and navigating networked knowledge organization systems. Over the years the NKOS members have discussed the four essential discussion points that was developed already at the second NKOS workshop in 1998:^[2]

1. The data model: what kind of data model is needed to support the interactive use of thesauri and other terminologies in online information services such as digital libraries? What data elements and/or relations are needed to convey the content of these resources?
2. The functional model: how do users want to use thesauri and other authority files in searching and resource description? What kind of access is important in exploring or “navigating” through the thesaurus?
3. Thesaurus-level metadata and thesaurus registries: what thesaurus-level metadata is needed to represent the scope, structure, size, ownership, access constraints, etc. of a thesaurus so that potential users will know what is available and how to access and use it?
4. The business/intellectual property model: what types of collaborative agreements and partnerships are necessary between thesaurus owners? What kinds of relationships are possible between owners of vocabularies published over a public network and users?

These topics have appeared at almost all workshops, and may be considered the main topical focus. Beyond these basic topics most of the workshops have had a special

theme in the call for proposals, with the purpose to cover proactively up-coming issues and problems relevant to networked KOS. During time the community has picked up emerging issues such as cross walks and vocabulary mapping, interoperability, user-centered approaches to design and development. Consequently, the NKOS community has covered KOS related issues from multiple perspectives. Table 1 provides an overview of all the workshops NKOS in the United States and Europe from 1997 to 2008, with indication of their special issues and themes.

THE NKOS WORKSHOPS AND SPECIAL SESSIONS

The main activity for the NKOS community is the NKOS workshops, with NKOS workshops in the United States since 1997 (US NKOS workshops) and in Europe since 2000 (EU NKOS workshops).

The very first NKOS workshop was held in the United States in June 1997 at the 2nd ACM International conference on Digital Libraries. Also the following workshops in 1998, 1999, 2000, and 2001 were hosted by ACM Digital Libraries Conferences. From 2001 the host was ACM and IEEE Joint Conferences on Digital Libraries (JCDL), continuing until 2005. After a break in 2006 and 2007, the 2008 US NKOS workshop was held as a Joint NKOS/CENDI workshop. CENDI: the Commerce, Energy, NASA, Defense Information Managers Group.

Joseph Busch, Taxonomy Strategies organized the first NKOS workshop. Later workshops were organized by a large group of people, with Linda Hill, University of California, Gail Hodge, Information International Associates, Marcia Lei Zeng, Kent State University, and Diane Vizine-Goetz, OCLC as the regular and primary organizers over the years.

From the start the workshops were international with participants from the United States as well as European countries. As a result, workshops were also held in Europe from 2000, still with broad international participation.^[3–6] The European Conference on Digital Libraries (ECDL) hosts the European workshops. Traugott Koch, Max Planck Digital Library, Douglas Tudhope, University of Glamorgan, and Marianne Lykke Nielsen, Royal School of Library and Information Science have been the principal organizers.

The NKOS workshops are peer-reviewed, with a formal call for proposals and a program committee. The organization group and the program committee are dynamic, and consist typically of a set of earlier organizers and new people, in order to keep simultaneously the primary scope and add new perspective. The program committee is multidisciplinary and international, and represents a wide range of professionals, disciplines, and interests.

Table 1 NKOS workshops, 1997–2008.

Workshop	Location	Workshop theme
US NKOS 1997	ACM Digital Libraries Conferences, United States	Metadata and thesauri
US NKOS 1998	ACM Digital Libraries Conferences, United States	Standards for networked terminology/thesauri/classification/authority systems
US NKOS 1999	ACM Digital Libraries Conferences, United States	Thesauri registry and data models
US NKOS 2000	ACM Digital Libraries Conferences, United States	Networked knowledge organisation systems, with special focus on ontologies and gazetteers
EU NKOS 2000	European Conference on Digital Libraries, Portugal	European initiatives and projects/options for global cooperation
US NKOS 2001	ACM Digital Libraries Conferences, United States	Classification crosswalks and vocabulary mapping
US NKOS 2002	Joint Conferences on Digital Libraries, United States	Digital gazetteers
US NKOS 2003	Joint Conferences on Digital Libraries, United States	Transformation of traditional KOS to new semantic tools
EU NKOS 2003	European Conference on Digital Libraries, Norway	Standards in networked KOS
EU NKOS 2004	European Conference on Digital Libraries, United Kingdom	User-centered approaches
US NKOS 2005	Joint Conferences on Digital Libraries, United States	Interoperability and integration of KOS
EU NKOS 2005	European Conference on Digital Libraries, Austria	User-centered strategies
EU NKOS 2006	European Conference on Digital Libraries, Spain	Semantic Web applications of KOS in Digital Libraries
EU NKOS 2007	European Conference on Digital Libraries, Hungary	KOS in next-generation digital libraries
US NKOS 2008	JOINT NKOS/CENDI, United States	New dimensions, e.g., mapping, collaborative KOS development
EU NKOS 2008	European Conference on Digital Libraries, Denmark	User centered systems and Terminology Registries

Source: <http://nkos.slis.kent.edu/> (accessed January 2009).^[1]

In 2004 the EU NKOS workshop was held in collaboration with Sebastian Ryszard Kruk, National University of Ireland, who comes from the semantic web community. The purpose was to have a special session, highlighting semantic web applications of KOS in Digital Libraries. The session was chaired by Thomas Baker, Goettingen State and University Library and Bernhard Haslhofer, ARC Seibersdorf research, Studio Digital Memory Engineering.

In 2003, 2005, and 2008 NKOS events were held three times yearly: workshops at JCDL in the United States and at ECDL in Europe, and NKOS Special Sessions at the DCxxx International Conference on Dublin Core and Metadata Applications (DCxxx). The first special session was held at DC2003 in Seattle. The session explored the relationship between metadata structures and values, and discussed the traditions and innovations in controlled vocabulary use in the networked environment. The second special session was held at DC2005 in Madrid, and focused on the practical applications of networked KOS. The last DC special session was held in Berlin in 2008. The presentations covered topics such as the combined use of KOS and social tagging, controlled vocabulary in metadata for semantic web usages, and metadata and terminology registries.

In 2008, the conference of the American Society of Information Science and Technology (ASIST) hosted a NKOS meeting, which was a new invention and meeting platform. The meeting was held as a panel discussion that addressed important issues around standards and applications. A registry for controlled vocabularies at the Library of Congress was presented, the architecture of the OCLC

Terminology Services, and a MeSH indexing tool for Health Science Repository System. The panel was a continuing effort of the ASIST Standards Committee in order to promote awareness of standards.

SPECIAL JOURNAL ISSUES

The workshops do not publish workshop proceedings, but publish the Power Point presentations at the workshop Web site.^[1] However, NKOS-related special issues have appeared in the online Journal of Digital Information (JoDI) in 2001 and 2004 and in New Review of Hypermedia and Multimedia (NRHM) in 2006. These special issues have their origin and evolve from the NKOS workshops where the participants are encouraged to submit papers based on their NKOS presentations. However, the calls for papers are open calls within the topical scope of networked KOS.

The first special issue of the JoDI evolved from the EU NKOS 2000 workshop, held in Lisbon.^[7] The focus was European initiatives and projects, and the issue presented five papers on the general workshop themes, on both conceptual aspects and technical implementations of knowledge organization systems. The papers covered the development of a four-language multilingual social thesaurus, exploration of the potential of thesaurus facet structure in query formulation, problems of semantic mapping between thesauri, approaches to the mapping and understanding of equivalence and hierarchical relationships between terms from different subdomains, and the use of the Unified Modeling Language (ULM) for

representing ontologies and mapping from Extensible Markup Language (XML) encodings and UML.

The second special issue was published in JoDI in 2004 with its origin in the two NKOS workshops, held in 2003 in the United States and Europe, respectively.^[8] Three of the five accepted papers represent classical NKOS topics. The first paper reported a reengineering project of a traditional thesaurus structure to an ontology structure for conceptual reasoning and automatic use. The second paper discussed automatic mapping and creation of intervocabulary associations, and the third paper concerned development of protocols for distributed access to thesauri. The fourth paper was a theoretical paper discussing the role of knowledge organization systems and arguing that the effective teaching of scientific concepts may be facilitated by digital library systems, which provide integrated knowledge organization structures. In the paper a system was presented, based on a strongly structured model of scientific concepts that integrates a domain-specific KOS with associated metadata and specialized learning models. The fifth paper reviewed the topical notion of the semantic web, and argued that the semantic web is based on a restricted and static sense of meaning. The last paper was long for a conventional journal paper, but as JoDI is an electronic journal, it was possible to publish the extended historical treatment of the semantic web. This is precisely in the spirit of the NKOS community that focuses on facilitating informal communication of new perspectives and viewpoints.

The third special issue was published in the *New Review of Hypermedia and Multimedia* in 2006. The issue had its origins in the EU NKOS workshops, held in 2004 and 2005, although the majority of contributions resulted from an open call for papers.^[9] The themes were typical for NKOS. One paper reported research evaluating automated subject classification of textual Web pages with categorization rules based on a controlled vocabulary. The second paper continued the automatic indexing theme by reporting on a variety of natural language processing techniques that have been used in combination to improve information retrieval, including query expansion. Semantic interoperability was the topical focus of the third paper that reported results from a major project by the Food and Agriculture Organization (FAO) in mapping two large agricultural thesauri. The fourth paper described a freely faceted classification method that allows the free combination of concepts in complex subject descriptors. A Web demonstrator illustrated its application to a small set of bibliographic records. The last paper reported on initial results from proof of concept projects conducted by the Metropolitan Museum of Art and the steve.museum collaboration.

The NKOS community has proposed and initiated the development of several working papers. Linda Hill and Interconnect Technologies drafted in 1996 document defining and describing a set of thesaurus attributes.^[10] A reference documents for data elements was developed in 1998, and later updated in 2001 and 2008.^[11] Gail Hodge

drafted a taxonomy of knowledge organization systems in 2000.^[12] A document describing a vocabulary mark-up language was published in 2000.^[1]

As a whole, the special issues and working papers represent well the objectives and topical focus of the NKOS community. All three journal issues are a mix of the classical NKOS topics related to the use and development of KOS and up-coming topics such as user-oriented approaches to design and development, social tagging, and KOS as a teaching facility. Similarly, the NKOS-related documents cover classical NKOS topics.

CONCLUSION

The analysis of NKOS community and its activities shows that the NKOS community is an active network which enables presentation and discussion of the use and development of KOS. The community is international and multidisciplinary with participants from a variety of fields such as information science, library science, computer science, semantic web community, and language engineering. Correspondingly, the participants come from academia as well as practice. The network facilitates informal interchange of ideas, viewpoints, and approaches by a diverse set of means, a Web site, mailing list, workshops, journal papers, and working papers.

The overall focus is KOS, but this topic is approached from many different angles, from technical issues to intellectual, semantic, and terminological problems, standardization and registries, from design, development, and use of KOS applications. NKOS is a topical broad forum, and provides room for completed and on-going research, early and mature development projects, and demos of prototypes as well as full applications. The review of the NKOS activities shows clearly that the community covers multiple KOS-related issues from a large set of disciplinary perspectives.

This topical diversity, multiple perspectives, and informality in communication should be considered an advantage in its richness and complexity, but the multiplicity might also be a disadvantage and “Achilles’ Heel,” with an implicit danger of lack of focus and mixed quality. However, it seems from the analysis of the activities and the fact that the community has existed more than 10 years that the more or less constant organizing committees in the United States and Europe, and the well established peer review process is adequate and sufficient to maintain satisfactory quality, attract participants, and keep focus in multiplicity.

New Zealand Aotearoa: Libraries

Heather M. Lamond

Massey University Library, Palmerston North, New Zealand

Abstract

This entry provides an overview of libraries and library services in New Zealand Aotearoa. Taking as a starting point British colonization in 1840, the entry follows the development through until the present day. In addition to outlining the four major library sectors of public, academic, school, and special libraries, it also includes detail of the National Library of New Zealand. Education for librarianship in New Zealand is described along with descriptions of professional associations. Finally, some issues and challenges in New Zealand libraries are identified.

INTRODUCTION

Situated at the bottom of the Southern Hemisphere in the Pacific Ocean, New Zealand consists of two major islands (North and South), and smaller surrounding islands. It was originally settled prior to A.D. 1300 by Polynesian people from the eastern Pacific islands. It is believed that they made landfall along the eastern coast of New Zealand^[1] (p. 35). For the ensuing almost 350 years, the indigenous people of Aotearoa lived without European contact or influence and a community with a strong oral history and tradition developed. The *tāngata whenua* (people of the land) Māori lived in independent subtribe groups.

The first European discovery in 1642 was by Dutch explorer Abel Jansen Tasman, who mapped portions of the west coast of both islands. Subsequently, some 120 years later, New Zealand was effectively rediscovered by British Captain James Cook in 1769.

The beginnings of European settlement were in the late 1700s and early 1800s, primarily by whalers and sealers, with the first traders and missionaries following shortly after. New Zealand became annexed to the British Crown in 1840 with the signing of the Treaty of Waitangi, and by this time there were only a few hundred Europeans living in the country.^[2] The Treaty is now considered the founding document of New Zealand Aotearoa as a nation. The British understood that the Treaty granted sovereignty to the British Crown, whereas the Māori chiefs that signed the document understood they were granting governance to the Crown but not sovereignty. The differences between the two versions (one in English and one in Māori) have been a point of tension and debate since 1840.

The wave of settlers that followed the declaration of British sovereignty were predominantly those looking for a better life than they were leaving behind, with an image of a society that was both egalitarian and equal. Literacy levels were relatively high among the settlers and those

who had low levels of reading ability were determined to better both themselves and their society.^[3]

New Zealand today has a population of over 4.8 million people. While it is truly multicultural, with recent high immigration rates from the Pacific, Asia, and the Middle East, the Treaty of Waitangi establishes a formal bicultural framework for Māori and Pakeha (non-Māori) to work within. To this end, New Zealand has three official languages—English, Te Reo Māori, and, since 2006, sign language.

The impacts of British colonization can be clearly seen in the government and the legislative structure. While there was a brief period of provincial government in the nineteenth century, this was short-lived, so unlike Australia and the United States, New Zealand does not have state or provincial government. This has led to more cooperative developments on a national scale.

New Zealand has a state schooling system that is free for all 5–19-year olds and compulsory for all 6–16-year olds.^[4] While achievement rates for New Zealand students in the OECD PISA reports are higher than average (ranked seventh in 2009),^[5] on closer inspection, the education system is not serving all students equally well. There are higher numbers, in particular, of Māori children leaving school before eighteen, and one in four New Zealanders over the age of fifteen does not hold any educational qualifications. Low literacy levels among Māori are an ongoing concern, and various Māori education initiatives have been developed over the years to address these gaps.

The New Zealand economy was traditionally based on primary industries, with a focus on agriculture, forestry, and fishing exports to drive the economy. In recent times, there has been a shift in focus for development with subsequent government investing in manufacturing innovation, the knowledge economy, and tourism. While the primary industries continue to make the most significant contributions to the economy, the newer areas of emphasis

are having an impact and are an attempt to spread the risk in times of recession and slow growth.^[6] New Zealand does suffer in terms of the global economy being geographically isolated from many of its major markets. The increasing financial cost of freight and concern about the environmental footprint of long-distance exporting places the country at a disadvantage when seeking new markets, as well as the barrier of trade protection measures in potential markets. Free trade negotiations are a priority for New Zealand governments, and it is a party to the Trans-Pacific Partnership Agreement negotiations.

While New Zealand is a well-developed first-world nation, in recent times, there has been increasing concern about levels of child poverty and a widening divide between the socioeconomic classes.^[7,8] Improving technology infrastructure is one method that is being proposed to address these gaps. Ultrafast broadband is to be rolled out nationwide by 2020.^[9]

LIBRARY ORIGINS AND LEGISLATION

The first library in New Zealand is thought to have been a Mechanics' Institute and Library that opened in Auckland in 1842,^[10] and in 1854, the first Provincial Council libraries were founded.^[10] The 1874 Census states that there were 161 public libraries and other literary institutes in New Zealand at that time. However, these were not public libraries as we know them now, but private members' collections. In 1879, the Auckland Free Public Library was formed from the previous Mechanics' Institute and was the first of its kind in the country with other centers following suit thereafter. By 1926, there were 435 public libraries listed.^[10] However, the majority of these libraries were still subscription based. In 1934, only the Timaru Public Library was lauded by Munn and Barr (a commissioned report on libraries in New Zealand) as being completely free for its constituents to use.

The General Assembly Library (established to meet the needs of central government representatives) was first established in Auckland in 1856, and subsequently moved to Wellington when the more southern city was established as the capital city in 1864.^[3] The National Library Service was initially formed in 1945 as an amalgamation of a collection of national services, and in 1965 was merged with the General Assembly Library and the Alexander Turnbull Library (a private collection gifted to the country) to become the National Library of New Zealand.

The first academic/tertiary library was established in Dunedin in 1869 at the then University College of Otago, with other centers such as Christchurch (1873), Auckland (1883), and Wellington (1899) following shortly after.^[11]

Much of the development of New Zealand libraries following the pioneer period was as a result of a report commissioned from the Carnegie Corporation by the New

Zealand Library Association (NZLA)—commonly known as the Munn-Barr report and published in 1934. A similar report was researched and written for Australia's libraries and published in 1935 (known as the Munn-Pitt Report). In addition to the recommendations of the Munn-Barr report, which governed the strategic development of libraries for the next 50 years,^[12] New Zealand was the beneficiary of several Carnegie grants to both build libraries and fund development of collections and librarians.

LEGISLATION

The primary piece of legislation governing public libraries in New Zealand has its origins in the original Public Libraries Act of 1869. It provided, in principle, for local authorities to be authorized to charge a rate for library funding, that management of libraries would sit with the local authority, and that admission to libraries should be free. The current legislation covering public libraries is the Local Government Act 2002, and in essence it lists a library as a core service for consideration (although does not obligate any local authority to provide a library), and states that where a library is provided, constituents must be able to join free of charge. While public libraries are in general free to join, there has been a history of some libraries charging for borrowing some items. This could stem from the original intent of the 1869 Act, when it was not envisaged that public libraries would be lending libraries.^[10] Recent lobbying attempts by the Library and Information Association of New Zealand Aotearoa (LIANZA) to ensure core library services are provided free of charge in all local authorities were not successful.

The National Library Act 1965 was enacted when the National Library Service amalgamated with the Alexander Turnbull Library and the General Assembly Library. This Act was repealed in 2003, and replaced with The National Library of New Zealand (Te Puna Mātauranga o Aotearoa) Act 2003.

Other legislations that impact on New Zealand libraries are the Copyright Act 1994 and associated regulations, privacy laws, classification laws, and laws and regulations concerning digital access. The New Zealand Bill of Rights Act 1990 is designed to protect citizens from discrimination and, although not an Act, the Treaty of Waitangi as a founding constitutional document plays a large part in guiding libraries' moves toward biculturalism.

NATIONAL LIBRARY

The National Library of New Zealand officially came into being in 1965, although its seeds were planted much earlier in a variety of national library services. Key among these was the Country Library Service (started in 1938), which sent bulk loans of books to small rural libraries. The

other key national service was the School Library Service that began in 1942. These two services were amalgamated in 1945 to form the National Library Service. Then in 1965, the Alexander Turnbull Library and the Parliamentary library were added and the National Library became an official entity.

The National Library of New Zealand has, as its purpose in The National Library of New Zealand (Te Puna Mātauranga o Aotearoa) Act 2003, to collect and preserve documentary heritage and taonga (treasures), to supplement and further the work of other New Zealand libraries, and to work collaboratively with other institutions having a similar role. The current work of the National Library is focused on providing easy access for all New Zealanders to the information and resources they need to turn knowledge into value.^[13]

In 2011, the National Library along with Archives New Zealand was integrated into the Department of Internal Affairs. In late 2012, the National Library reopened to the public after a three-year refurbishment of the building and service. During the closure, mass digitization projects were undertaken that now provide over 250,000 online images and two million pages of historical newspapers. More than 2000 at-risk audio recordings were also digitized during this period.

In its role of working collaboratively and furthering all New Zealand libraries, the National Library has been the driving force behind several major innovative projects. Highlights include the following:

- Te Puna Services—a partnership with New Zealand libraries that facilitates shared cataloging, inter-library loan, and the maintenance and searching of the National Union Catalogue (<http://natlib.govt.nz/librarians/te-puna>).
- EPIC (Electronic Purchasing in Collaboration), which provides access to a range of online databases to libraries in a collaborative purchasing model (<http://www.epic.org.nz/>).
- DigitalNZ is a collaboration between more than 120 partners to make access and discovery of digital content relevant to New Zealand easier (<http://www.digitalnz.org/>).
- Aotearoa People's Network Kaharoa (APNK) provides free access to broadband internet services via public libraries and marae around New Zealand (<http://www.aotearoapeoplesnetwork.org/>).
- Kōtui is a shared library management system and discovery service that public libraries can join by subscription, thereby reducing cost to individual libraries and increasing shared capability and knowledge (<http://www.kotui.org.nz/>).

The Library is also working with New Zealand publishers and other stakeholders on e-publishing and e-lending models in order to establish a workable solution to the

issue of ebooks in libraries. Through Services to Schools (<http://natlib.govt.nz/schools>), the National Library provides critical literacy and resourcing support to teachers and students throughout the country.

The collections of the National Library are both heritage and general. Under the legal deposit clause in the National Library Act 2003, two copies of all material published in physical format are to be sent to the National Library for the collection. The general collections are primarily held and developed to support the Library's reference services and the Services to Schools collection. Heritage collections include the Alexander Turnbull Library (see below) and other collections of material significant to the history of New Zealand.

The Alexander Turnbull Library

A “library within a library,” the Alexander Turnbull Library began life as the private collection of Alexander Horsburgh Turnbull, born in Wellington in 1868. By the time of his death in 1918, the collection held 55,000 items including books and other print items that he bequeathed to the Crown to “form the nucleus of a New Zealand National collection”^[14] (p. 1). The collection has been added to continually over the years with a strong but not sole focus on information relating to New Zealand and the Pacific. It also includes an outstanding collection regarding John Milton—a particular interest of Turnbull's. Most of the material in this collection is for use in specialized Reading Rooms within the National Library building and it is predominately a closed access collection as befitting its value and worth.

PUBLIC LIBRARIES

New Zealand's public libraries are administered and funded solely from local government. There are 290 local public libraries across 78 local authorities and the range in size, scale, and capability is vast. Auckland Libraries (formed by a local government amalgamation in 2010) is the largest public library system in Australasia with 55 library branches across the system. As outlined in the legislation section, there is no legislative requirement for a local authority to provide a library service, but in reality, most people have access to a public library within their region. Libraries are funded usually from a levy made on property owners, which is gathered by the local authority. This local government funding usually contributes around 80% of the library's annual income. Further income is generated from overdue loan penalties and value-added services such as business research services and digital collections.

With the cessation of the Country Library Service in the late 1980s and mass local government amalgamations in 1989, it became unviable for many small rural libraries

to continue as a local government function. In an echo of the subscription libraries of the pioneer days, some of these libraries have continued to function as community membership libraries.^[15]

LIANZA published Public Library Standards regularly, with the most recent edition in 2004. With the establishment of an independent Association of Public Library Managers (APLM) in 2007, the updating of the Standards has become a priority for this group to undertake, and at the time of writing, these are yet to be published. In 2012, APLM released the refreshed Strategic Framework for Public Libraries 2012–2017, which outlines a bold direction for the sector in coming years. The eight key priorities from the framework for the coming five years are to

- Work with New Zealand authors, publishers, and booksellers to develop a whole-of-country approach to deliver an ebook solution that meets the needs of all parties
- Develop an evidence-based model of measurement that can be used to demonstrate public libraries' value and contribution to outcomes and for benchmarking purposes
- Identify or develop business models that make it easy for collaboration on a regional, national, and cross-sector basis in association with the local government New Zealand
- Explore a nationwide partnership with schools to deliver content and reading support in schools and across the Network for Learning, in association with the Ministry of Education and the National Library of New Zealand
- Collaborate with the National Library of New Zealand to deliver a National Year of Reading program to celebrate the joy of reading and improve literacy levels in New Zealand
- Develop a national approach to workforce planning, skills development and recruitment, and, in association with LIANZA, foster leadership for the new generation of libraries
- Investigate the opportunities for the development of whole-of-country digital solutions to ensure public library content and services are delivered in the mobile environment
- Dramatically increase the range of New Zealand's unique and legacy content available in digital format, in association with the National Library of New Zealand, universities, and other appropriate national and international partners^[16]

Services provided in New Zealand public libraries include lending and reference collections in many formats (e.g., DVDs, CDs, MP3, ebooks, online databases, and research tools). Many provide mobile libraries in order to serve communities that are further away from their physical branch as well as outreach services to community

members with special needs. Through the APNK free internet access is provided at 149 sites around the country, with libraries that are not part of the network also providing internet access, although non-APNK libraries sometimes charge a small fee for access. Children's and young people's services are offered nationwide, and many public libraries work closely with their local schools to provide tailored programs and services at appropriate levels. Provision of ebooks through public libraries is increasing in New Zealand, primarily through a consortial approach to purchasing and local solutions.^[17]

The reinventing of public libraries as community spaces or hubs has been a recent and strong development in New Zealand, with many libraries being either refurbished or moving in to completely new buildings in the last decade or so. The library as place has led to new models of community service being provided from library buildings, such as community meeting rooms, flexible furniture, cafeterias, and multimedia computing suites, and of course the expert help that goes along with them. There have also been some significant developments bringing libraries, museums, and galleries into one space (e.g., Puke Ariki in New Plymouth) as well as some libraries providing services that have traditionally been provided by local authorities (e.g., rates payments, dog registration, cemetery records, etc).

SCHOOL LIBRARIES

While there are more than 2550 school libraries across all age levels of the compulsory sector, it is not a legislative obligation of schooling in New Zealand to provide a library service. As schools have considerable freedom in how they manage their own environments and budgets, the quality of any school library can vary greatly from school to school. School libraries in the main suffer from being both underfunded and undervalued in many schools in the country, with the importance of professional, qualified staff not uniformly recognized or understood.^[11] Of course, there are exceptions of well-funded and supported school libraries, but these are not common, and in the LIANZA Remuneration Survey, school librarians are the lowest paid of all sectors across all roles.^[18]

Both the School Library Association of New Zealand (SLANZA) and the National Library are active proponents in this sector. SLANZA provides advocacy and professional development for those working in school libraries through a range of resources and events. The National Library, through the Services to Schools section, provides a range of support services to schools, librarians, teachers, and learners. These include a curriculum service where resources are sent to schools around the country to assist teachers and school librarians in teaching the curriculum. They also provide advisory services to teachers and school

librarians as well as offering an online chat reference service to students called “Any Questions.”^[19]

The New Zealand curriculum identifies five key competencies: thinking; using language, symbols, and text; managing self; relating to others; and participating and contributing.^[20] While these concepts are very broad, it is possible to place developing information literacy skills and using library resources effectively within them. School librarians face an ongoing advocacy challenge to build strong working relationships with both school management and teachers to embed information and research skills in to day-to-day teaching.

In 2012, the New Zealand Government requested that the Education and Science Select Committee carry out an “Inquiry into 21st century learning environments and digital literacy.”^[21] Following submissions to the Select Committee by SLANZA, LIANZA, and various individual libraries, it is encouraging to note that the important role of both school and public libraries in the twenty-first century learning has been highlighted as an area for further investigation by the government.

ACADEMIC LIBRARIES

New Zealand’s tertiary education system is made up of eight universities that are public institutions; eighteen government-funded Institutes of Technology or Polytechnics (ITPs) that offer tertiary education with a focus on technical, vocational, or professional education, but also encourage research particularly in applied or technological areas; and three Wānanga (Māori teaching and research institutions) with sites throughout the country. While all tertiary institutions receive government funding, most (especially the universities) seek additional revenue through research and development and other commercial initiatives. Government funding is currently allocated according to four broad education performance indicators: qualification completion rate, course completion rate, retention, and progression. In addition, a stand-alone government fund, the Performance Based Research Fund (PBRF), is allocated according to the standard of research output from an institution.

While the Munn-Barr report of 1934 stated that “[t]he college libraries of New Zealand do not even approach accepted overseas standards”^[10] (p. 35), the same cannot really be said today. Development in the university libraries took a turn for the better in the 1960s, with increasing budgets for building collections that were relevant and necessary for the teaching and research activities of their institutions. This was a result primarily of the Parry Report^[22] that urged an immediate injection of funds to libraries. It was not, however, until the advent of electronic access to scholarly databases and later full-text online academic journals that vast improvements were seen. University libraries are still subject to the constant

vagaries of budget allocations from the university and ever-increasing subscription costs. In recent times, the open access movement has offered alternatives for both scholarly publishing and scholarly collections of university libraries.

All the university libraries contribute to the New Zealand interlibrary loan scheme, and there are also reciprocal borrowing arrangements in place between most of them. Consortial purchasing of electronic packages increases the buying power for what is still a small market by working with universities in Australia through the Council of Australian University Librarians Electronic Information Resources Consortium (CEIRC), of which all the New Zealand university libraries are members.

The ITP libraries have also had mixed fortune since their establishment in the 1960s as technical institutes. Woefully underfunded during this stage, the institutes were widely criticized for the state of their libraries. The 1990s saw a loosening of control by the central government over the qualifications and courses that the ITPs could offer, and this era saw them begin to offer undergraduate degree courses. In order to be accepted as meeting New Zealand Qualifications Authority (NZQA) standards significant, investment in their libraries was required, and many ITP libraries experienced phenomenal growth as a result.

As with the university libraries, the ITP libraries continue to struggle against variable funding and increasing vendor costs. As subsequent governments continue to review and alter tertiary education policies, these all have a flow-on effect to the library budget.

Wānanga were established in the early 1980s but were not officially recognized under the Education Act 1989 until the early 1990s. Wānanga were established to provide a tertiary education option for Māori, which was a distinct experience from the mainstream universities and ITPs. The rationale for wānanga can best be stated as “. . . characterized by teaching and research that maintains, advances, and disseminates knowledge and develops intellectual independence, and assists the application of knowledge regarding ahuatanga Māori (Māori tradition) according to tikanga Māori (Māori custom).”^[23]

As tertiary academic institutions, all three types of libraries offer similar services to their patrons, including lending, reference services, information literacy teaching, collection development and management, and ensuring access to large collections of print and electronic resources. Increasingly, the academic library is taking on other roles such as computing and learning services and providing flexible spaces for group research and projects. Several institutions have had major refurbishment to match the new vision of what an academic library is. Discovery services are a relatively new development in terms of providing access to resources for patrons as libraries continue to strive toward a solution that delivers quality results to users in the most painless way possible

and are still a work in progress in many institutions. Other recent developments are focusing on embedding library and research skill development into the online learning environment using teaching and learning pedagogy and tools, developing digital institutional repositories, and starting to work with researchers in the e-research field.

SPECIAL LIBRARIES

Special libraries exist to meet the information needs and requirements of their parent bodies. Included in this group are libraries serving government departments, medical libraries, corporate and law libraries, as well as those from the not-for-profit sector. They can be described as having a narrow scope in both collection and online resources, but greater depth to that collection than is possible in a more general library.

There are approximately 300 libraries in this sector in New Zealand, the earliest of which can be traced back to the establishment of the nation with various court libraries and scientific collections, including those of the Royal Society of New Zealand.^[10]

Special libraries are in general funded directly by their parent body, and some have needed at times to be very inventive to raise additional funding with initiatives like accepting overseas interns for a fee and even teaching English in overseas centers. In an increasingly tight economic climate, special libraries need to work very hard to demonstrate their value to their funders, particularly when there is a common misconception that everything is available on the internet. By developing subject-specific expertise in the required narrow fields of knowledge, special librarians help to preserve their role, but they also need to be vigilant in marketing their specialist skills and services to their clientele. There has also been a broadening of role as evidenced by the increasing variation in position titles from librarian to information manager or knowledge manager. While some corporate libraries have been lost over the last decade, it appears there has been an increase in special library workers in the noncommercial sector.^[24]

Of particular significance in this Sector are the Crown Research Institute (CRI) libraries. There are eight different institutes, each with a specialist research library service to meet the needs of scientists and technicians working in their fields to further research in areas such as environmental, agricultural, and food research.^[25]

The Parliamentary Library that began as the General Assembly Library in 1856 was part of the National Library from 1965 until 1985. It was felt then that separating the Library out again would help to clarify its purpose as the library for parliamentarians,^[3] and in 1986, its name was changed from the General Assembly Library to the Parliamentary Library. While the Library had in the past fulfilled many of the roles of a National Library, since the separation, it has been able to focus much more on

providing an efficient and effective information service to members of parliament, parliamentary staff, and research units from its vast collections of both print and digital material as a special library.

EDUCATION AND THE PROFESSION

Education for Librarianship

As a result of New Zealand's geographical isolation, the education of librarians was a concern as early as 1910, when the first NZLA Conference set one of their aims to be to improve the "status and qualifications"^[26] of New Zealand librarians. Given that there were no library training opportunities within New Zealand, this invariably meant travel to either the United Kingdom or the United States.

By 1942, the NZLA was ready to offer a general certificate course by correspondence, and there were forty-six students in the first intake. It was a requirement for enrolment that students must be currently employed in a library for at least fifteen hours a week and the nature of the course was both practical and theoretical. In 1946, the first postgraduate diploma was offered and was taught from within the National Library Service from the then newly formed New Zealand Library School. The Diploma was considered a professional qualification and would take one academic year of full-time study in Wellington.

This model of library education and training was to remain in place for almost a further 40 years. After several years of discussion and planning, the Certificate course moved to the Wellington Teacher's College and the Diploma to Victoria University of Wellington in 1980.^[27] Since 1980, most qualifications have been renamed as information management courses, the Diploma has been upgraded to a Master's degree, and a Doctor of Philosophy degree has been introduced. In 1996 the undergraduate education was moved to the Open Polytechnic of New Zealand.

The Victoria University of Wellington is the only educational provider offering postgraduate qualifications. Current options are postgraduate certificates and diplomas, in addition to the master of information management degree with a library science endorsement. Victoria also offers the option of PhD study in the School of Information Management, although there have been very few enrolments focusing on topics in librarianship to date. Victoria courses are offered both by distance education and on campus in Wellington.

The Open Polytechnic of New Zealand offers subdegree programs in LIS as well as undergraduate bachelor of arts or applied science degrees in library and information science. The Open Polytechnic is a distance education provider.

Te Wānanga o Raukawa offers a one-year diploma or a three-year undergraduate bachelor degree in information management, with a specific aim to develop bilingual and bicultural managers of Māori information resources in Māori and non-Māori organizations.

Professional Registration

After several years of debate, planning, and consultation around the need to improve the standing of librarianship as a profession, in 2007, LIANZA introduced its Professional Registration scheme. The scheme is an open, voluntary scheme that provides a framework for continuing professional development and accreditation with like organizations outside New Zealand. It is designed to firmly position library and information management as a graduate profession, as registrants must hold a recognized degree in library studies. Similar in structure to CILIP's Chartership scheme, the Professional Registration scheme required registered librarians to revalidate every three years by submitting a reflective journal of development and learning. While still relatively new, the scheme aims to benefit librarians, employers, and the public as a whole by providing both the motivation and means to continually upskill. LIANZA's scheme has reciprocal recognition with CILIP, allowing registered New Zealand librarians to be recognized as equivalent to chartered librarians in the United Kingdom.

The LIANZA Professional Registration scheme has a body of knowledge adapted from the IFLA guidelines, with the significant addition at the time of an eleventh element regarding indigenous knowledge frameworks. Both LIANZA and Te Rōpū Whakahau (an association for Māori library workers) have worked diligently to have this eleventh element internationally accepted as part of the LIS Body of Knowledge with the support of the IFLA SIG on Indigenous Matters, and they are to be congratulated that this amendment to the IFLA guidelines has been made in 2013.

Professional Associations

The NZLA, trading as LIANZA, came into existence in 1910 in Dunedin, following the first conference of library leaders. It was incorporated under its own statute, NZLA Act 1939, and celebrated its centenary with the publication of the Association's history in 2010.^[26] LIANZA is a membership organization with both individual and institutional members and has as its vision to "... be the vibrant, vital professional voice for those engaged in Librarianship and Information management."^[28] LIANZA operates the Professional Registration scheme for librarians and information professionals as well as providing an annual conference, continuing professional development program, regular publications, and high-level advocacy on behalf of members with central and local government.

Te Rōpū Whakahau was formed in 1992 as a SIG of LIANZA and in 1996 was incorporated as an independent organization. It was formed as a specialist support network for Māori staff working in libraries and to build understanding and capacity for all when working with Māori patrons or Māori information. There is a formal partnership between LIANZA and Te Rōpū Whakahau that assures the two associations' work together in the pursuit of bicultural development of librarianship in New Zealand. Notable achievements for Te Rōpū Whakahau have been the development and delivery of CPD courses nationwide to increase bicultural awareness in LIS workers, working with The National Library of New Zealand to develop Māori subject headings for use in library catalogs, and working with Te Wānanga o Raukawa to deliver library education in a Māori environment.

Over the decades, other professional associations have come into being to serve specific needs and sectors. Notable examples are the SLANZA, APLM, and the New Zealand Law Libraries Association (NZLLA). Sector specific groups are also in existence within LIANZA's structure in the form of Special Interest Groups (SIGs) and these include HealthSIG, SLIS (Special Libraries), and the Digital Libraries SIG, to name a few.

Issues and Challenges

Biculturalism

As described earlier, New Zealand is in the unique position of having a founding document in the Treaty of Waitangi that essentially requires two distinct cultures to live as equals in one nation. The reality of colonization is of course quite different to this ideal, and true biculturalism remains a challenge for the country as a whole.

Since a resurgence of Māori culture and language in the late 1980s, there has been considerable movement along the bicultural continuum in libraries and information services. Two key research reports have contributed to these developments "Te Ara Tika: Maori and Libraries" and "Te Ara Tika: Guiding Voices."^[29,30] The project that led to their publication during the 1990s was jointly commissioned by LIANZA and Te Rōpū Whakahau.

Evidence of the development of bicultural library services includes such practical things as bilingual signage, bilingual staff, special and separate collections of Māori material, Māori artwork, and adhering to the Treaty of Waitangi appearing in libraries' strategic plans and goals. With the twenty-first century has come a deeper commitment to understanding of a Māori worldview in many leading institutions. For example, the National Library's "Bicultural Implementation Plan" shows great potential.^[31] Te Rōpū Whakahau continues to work toward helping non-Māori library staff achieve authentic

bicultural understanding and knowledge, but maintaining this momentum will be a challenge for some time to come.

The Waitangi Tribunal is a central government body established to settle claims brought against the Crown by Māori under the Treaty of Waitangi. A recent report (WAI-262) on a claim relating to ownership of intellectual property and cultural treasures or taonga makes it clear that in order to truly meet the needs of Māori, libraries need to consider not just the services offered to Māori clients but also how Māori information and knowledge is cared for and preserved.^[32] Having a deep understanding of the indigenous knowledge frameworks at play is critical to achieving this.

The Digital Revolution

As we enter the twenty-first century, all libraries face the challenge of remaining relevant in the digital world. As the general purpose of libraries has not changed, the challenge in particular is demonstrating relevance and value to stakeholders and decision-makers that fund libraries. These challenges are felt just as strongly in New Zealand as in the rest of the world. A particular vulnerability for New Zealand public libraries is the lack of any legislative obligation for local authorities either to provide public library services or to ensure that those services are provided free of additional charge. As costs continue to increase and local authorities must spread levy income further, libraries can seem an easy way to cut spending, especially when there is a common misunderstanding of the continued importance and relevance of libraries in the digital age. This misconception is common across all library sectors.

The digital divide in New Zealand (due both to the physical lack of high-speed broadband in remote areas, and the comparatively high cost of data traffic) is both an opportunity and challenge for New Zealand libraries. Libraries are well placed to help address the divide (if they are funded to do so), but, at the same time, they will inevitably move to providing more services that are only available online, thereby underserving some parts of the population and further exacerbating the issue. Of course, at the same time libraries support developing their customers' information and digital literacy skills as part of their everyday work, and this will go a long way to bridging the digital divide.

As more and more information is created online and shared on the internet, there will be an increasing need to address the preservation of digital New Zealand knowledge and information for future use and research. With the National Library undertaking a biannual all-of-domain web harvest and maintaining the National Digital Heritage Archive (NDHA), steps are being taken that are both sustainable and forward-looking. Many institutions also maintain digital repositories of local research and theses, as well as a community "kete" or repository movement

gaining momentum to capture local stories, images, and media. Of course, in relation to the discussion on biculturalism, automatic harvesting of digital content can be a fraught process where different ownership or intellectual property paradigms are in place, and this will need to be handled carefully to fall within the WAI-262 settlement guidelines.

CONCLUSIONS

Since the earliest days of pioneer settlement, New Zealand's libraries have struggled in an environment of both geographic and intellectual isolation. The Munn-Barr report of 1934 was very disparaging of the situation then but provided a clear path to improvement that was followed for a further five decades. The National Library of New Zealand, LIANZA, and leading libraries have since also provided insightful, innovative, and at times, groundbreaking leadership in the profession.

New Zealand has at times led the world, for example, in nationally acknowledging the importance of indigenous knowledge frameworks, developing an all-of-country digital preservation strategy, and establishing collaborative library purchase and collection agreements. Indeed at times, the nature of being an isolated, small country has been of benefit, allowing more agile, creative solutions to be formulated and implemented relatively quickly.

New Zealand libraries and librarians face the same challenges of underfunding and misconception that all libraries face in the twenty-first century, and they will need to meet these challenges with strength of purpose and commitment for many years to come, while continuing to innovate and think creatively to remain as Munn and Barr put it in 1934, the "community storehouses of knowledge and culture, not in the sense of compulsory educational institutions but as places where people may obtain help, self instruction, or recreation whenever they require it."^[10]

Non-governmental Organizations and Information

Lynne M. Rudasill

Steve W. Witt

University of Illinois at Urbana-Champaign, Champaign, Illinois, U.S.A.

Abstract

The advent of global civil society has highlighted the importance of the nongovernmental organization as a factor in the development of the information society. Understanding this phenomenon is essential for those interested in the dissemination of information surrounding various actors in civil society. Here we define the nongovernmental organization, discuss the different types of nongovernmental organizations and the areas in which they are active. The development of these organizations is discussed as well as future scenarios. Most importantly, the place of these organizations in information society, and interaction of the organizations with libraries, archives, and others in the pursuit of free and equitable access is explored.

INTRODUCTION

Nongovernmental organizations or NGOs are sometimes thought to be prominent examples of the effects of globalization. These organizations are ubiquitous in the world of interconnected, interdependent social movements. The mention of any major natural disaster brings to mind the work of the International Federation of the Red Cross and the Red Crescent Societies. Humanitarian relief efforts frequently include the work of Oxfam or Doctors without Borders. Environmental threats often find Greenpeace at the forefront of the fight to publicize and remedy the results. In 1997, the International Campaign to Ban Land Mines received the Nobel Peace Prize as had three other organizations before it. All of these organizations are examples of international NGOs.

What is an NGO? When and why did they develop into major players on the world scene? Why are they important to libraries and information science? How do they interact with individuals, states, and other international organizations? What do they do?

DEFINING THE NONGOVERNMENTAL ORGANIZATION

The problem with defining a term like “nongovernmental organization” is very similar to that of defining other self-referential terms. Although it seems simple at first, the mere definition of the term does not express the wide ranging implications of the concept. Literally, a nongovernmental organization might be assumed to be any group that is not part of a state organization and does not receive direct funding from a state government. This simple definition would include a wide range of organizations from humanitarian relief agencies to criminal syndicates, from religious organizations to multinational

corporations. Further exploration of the term provides us with a little more specificity. Generally, these organizations are privately funded, either directly through philanthropic organizations or individual members. Occasionally, however, government may play a role in their funding, or use the NGO as a funnel for distribution of assistance. In many countries, the state plays a role in the development and certification of NGOs. The missions of NGOs tend to focus on the remediation of some societal problem, or publicize some perceived injustice. They have alternatively been referred to as “the conscience of the world” or the “warning voice.”^[1] Several themes are repeated when attempting a more granular meaning for the NGO. They are not entirely governmentally supported or founded, although government policies might have been a major reason for their genesis. They usually have defined goals and objectives relating to the creation of a civil society. They frequently work at the grassroots level to provide aid, education, and, most importantly for the librarian, information both to the audience they are trying to provide services to, and to a wider audience of policymakers, state organizations, funding agencies, and actors on the international stage. The most useful advocacy tool of any NGO is information. Whether it is in the form of pamphlets distributed to a target population, a report to a funding agency, a public relations campaign, or a policy planning interaction with other organizations, the dissemination of information is key to the work of any NGO.

There are also many variants to the basic concept of the NGO. Related non-state actors include a variety of organizations such as the donor-organized nongovernmental organizations (DONGO), the governmentally organized nongovernmental organization (GONGO), the quasi nongovernmental organization (QUANGO), the grassroots organization (GRO), and the intergovernmental organization (IGO). They can be international in nature, or very local. After the antiglobalization riots during the

WTO economic summit in Seattle in 1999 the term “wild NGOs” came into use to denote NGOs that sought change through less-than-peaceful means of protest. Table 1 lists many of the terms and formats of these organizations including those terms used in several different countries.

The areas in which NGOs are active include a list of societal issues such as human rights, economic, and agricultural development, education, humanitarian relief, environmental degradation, health, international security, and economic development. Several of these areas are explored in depth later in this essay. NGOs might be social movement organizations, grassroots groups, religious organizations, or even the philanthropic organizations that fund other NGOs.

HISTORY OF NGO DEVELOPMENT

It should be noted that at one time, the theory of state sovereignty provided no recognition for organizations outside of other sovereign states as power-holders. The state

Table 1 Typology of organizations.

BINGO—Business NGO
CBO—Community-based Organization
Citizens’ Organizations—Local NGOs (commonly used in Japan)
Civic Advocacy Organization—Frequently used to refer to community-based organizations in the United States
CONGO—Conference of NGOs in Consultative Relationship with the United Nation
CSO—Civil Society Organization
DONGO—Donor-organized nongovernmental organization (can be governmentally organized, United Nations organized, or private)
GONGO—Government organized nongovernmental organization
GRINGO—NGO with a symbiotic relationship with a government
GRO—Grassroots Organization
IGO—International governmental organization (e.g., the United Nations, World Trade Organization, OECD, OAS)
INGO—International nongovernmental organization (e.g., Red Cross/Red Crescent, Oxfam, Amnesty International)
NGDO—Nongovernmental Development Organization
NGO—Nongovernmental Organization
NPO—Non-Profit Organization (used in United States frequently for philanthropic organizations)
PANGO—Party-affiliated Organization (mostly Latin American)
PDO—Private development organization
PSO—Public Service Organization
QUANGO—Any organization that relies on government funding, but is administratively distinct from the state
SMO—Social Movement Organization
VO—Voluntary Organization
“Wild” NGO—Newly developed NGOs interested in the negative effects of globalization

and its leaders interacted with other states in the development and application of policies both within and outside of its borders. This is sometimes referred to as the Westphalian model of sovereignty. In the late nineteenth century, non-state actors began to influence policy-making and intergovernmental relations. These organizations evolved into today’s nongovernmental organizations. One of the ultimate purposes for the NGO is to earn a place at the table when local, national, and international policy-making is taking place. This has truly changed the dynamic of the relationship between the NGO and the state.

The development of NGOs before and after World War I was quite rapid. Whether in spite of, or because of, the devastating “War to End All Wars” and the Great Depression in the United States, the growth in the number of NGOs was quite steady in the first three decades of the twentieth century. The 1940s saw the advent of the NGO as a recognized societal actor. But the true political power of these organizations was yet to be realized. Exponential growth in the number of NGOs occurred at the end of the twentieth century. The Yearbook of International Organizations first listed nongovernmental organizations, in 1949. The three categories of nongovernmental organizations listed there totaled 73 organizations in all.^[2,3] In the 2008–2009 edition of the work, 11,859 organizations were noted as Cluster 1 NGOs.^[4] It is interesting, but not surprising, that the rapid multiplication in the number of NGOs coincided with the expansion of the Internet as a tool for the dissemination of information.

Few publications concerning NGOs existed before the 1950s. The Online Computer Library Center’s (OCLC) WorldCat lists 49 books and 114 serials published for the time period between 1900 and 1950 if one searches for “nongovernmental organizations” as a keyword search. The decade between 1990 and 1999 shows 7553 book records and 209 serial records in the database. A search for the first half of the current decade reveals almost 5437 books and 96 serials records.^[5] Clearly, in recent years, publications by or about these agents of civil society and change have increased almost as exponentially as the organizations themselves.

This growth can also be seen in the relationship between NGOs and the United Nations. When the United Nations was chartered (itself an international governmental organization), 44 NGOs were legitimized through the authority found in Article 71 of the UN Charter. This entry states:

The Economic and Social Council may make suitable arrangements for consultation with non-governmental organizations, which are concerned with matters within its competence. Such arrangements may be made with international organizations and, where appropriate, with national organizations after consultation with the Member of the United Nations concerned.^[6]

In addition to this mention, Resolution 288 B(X) provided consultative status to recognized NGOs in 1950. In 1968, ECOSOC Resolution (XLIV) further defined this relationship and Resolution 1996/31 established three categories of consultative status—general consultative status; special consultative status; and inclusion on the roster. Most recently, the Millennium Declaration provided a new mandate to enhance the partnership of the NGOs and the United Nations.^[7,8]

At the state level, different nations have different reactions to the development of organizations within their boundaries that seek to share power. In more democratized areas, these reactions range from encouragement to benign neglect. In other cases, the development of organizations that give voice to the intrinsic problems of an area is frowned upon and varying controls are in place to prevent any thought of power sharing or governmental influence by these organizations. In still other states, the development of NGOs is fostered and sometimes the goals and influence of the organization are coopted for political ends.

THE PROS AND CONS OF THE NGO

Traditionally NGOs have been held in high regard by many governments and intergovernmental organizations, as well as individuals. There are three empowering aspects of NGOs. First, they are seen as having a good deal of expertise in the area to which they relate. The data produced by NGOs in exploring their target population or issue provides them with a great deal of information concerning the problems, issues, and policies that might be necessary to obviate a perceived need. Second, and related to this expertise, is the credibility they have in the promotion their agendas. They have been seen as free from the pressures that might arise from government funding or close ties to a business or industry. Even when the NGO is employed as a way of pushing government aid out to a population, the organization itself is considered an independent and frequently more efficient avenue for distribution than the state. Examples of this are particularly apparent in the delivery of humanitarian aid after natural and man-made disasters. Finally, many NGOs are perceived as having broad and effective networks to deal with problem issues. Although there are some exceptions, primarily due to cultural conditioning, NGOs are very good at reaching out to other organizations for both moral and financial support. The relationship between mass media and the NGO is usually a strong bond due to the importance of public relations for the organization and the issues it addresses.

In recent years, especially since the events surrounding the WTO-associated riots in various countries, the image of the NGO as an independent, peaceful change agent has been somewhat tarnished. The “wild NGOs” active in

these events frequently represented more radical even anarchist movements. In addition to behavioral problems, some questions have arisen regarding the accountability of many of these organizations. Less-democratic governments have used this as an excuse to shut down or at least severely limit the work of many NGOs. The existence of funding outside of the sphere of the state can be perceived as a threat and many instances exist of government policy interfering with the work of the NGO that receives its funds from an agency beyond its borders. Regulations for reporting are becoming more common in the state-NGO relationship.

NGOS AND INFORMATION

Information Dissemination

Other than increasing the amount of material written about NGOs, what impact do these organizations have on the library, the archive, or the larger information society? These organizations are both producers and consumers of large amounts of sometimes difficult-to-capture information. Ostensibly, grassroots organizations seek to send a flow of information downward to the clients and interested parties affected by the group. Information on weather patterns, water resources, health, and human rights are pushed out to the target populations. In this way, the NGO creates and disseminates information for its client base. This client base is also frequently the source of information the NGO needs to engender awareness of the issues and problems in its area of expertise. Using the client-generated information, NGOs must also push information upward to funding agencies, government agencies, and the international community for the purposes of financial support and influence. Information flows between the funding body and the organization in the form of reports, grant requests, and information bulletins. If the NGO has an affiliated relationship with a larger body such as a coordinating council or other international governmental organization an exchange of ideas, plans, statistics, or other information types is shared. Additionally, information may flow to a larger audience through publications and media outlets. Frequently, the information generated by the local agency will be passed up an information avenue to a coordinating council and ultimately to a supranational agency such as the United Nations for consideration in policy planning. A variety of information flows can be seen in Fig. 1.

Information Types

The production of information comes in many forms and formats. Information outflow from the organizations to funding and state agencies can include physical and financial progress reports, narrative reports, annual reports,

Fig. 1 Information dissemination.

annual budgets and work plans, published studies, internal studies, baseline and impact data, participatory appraisals, process documentation research, internal evaluation exercises, records, diaries, “significant changes,” field notes, dialogue with community members and field observations, and meeting minutes. The funding agencies for the NGOs studies provide project and program proposals, documents describing program strategies and interests, annual budgets and “summary justifications,” news clippings, trends, and networks, workshops and fairs, publicity documents, meeting minutes, field visit reports, evaluations and reviews, consultant reports/expertise, and monitoring missions.^[9]

Some of these documents may be a matter of public record, but most are not. Most of these documents are typical examples of grey literature. They are not widely distributed, and do not easily find their way into the traditional publication cycle. Those that are actually created electronically are rarely archived, and often difficult to find due to the lack of technological know-how on behalf of their creators. A researcher may come across a report during a field interview, and then be unable to obtain a copy when returning home. The temporary nature of these documents is of concern for the scholar and researcher as well as the librarian or archivist.

More easily accessible materials are frequently those that the organization uses to provide public relations and outreach for its clientele or cause. Well-established and financially supported organizations can often afford to maintain some kind of Web presence. In some cases this presence consists of basic information about the program, how to contact staff, and a mission statement. More robust sites include publications such as reports and newsletters, press releases, mailing lists, donor information, and a variety of policy statements. Although the information on these sites is more accessible, it is not always as stable as the print materials an organization might produce, and is subject to becoming inaccessible over time.

Following is a description of information flows of some of the types of NGOs whose information is widely sought or interact regularly with information professionals and librarians.

Human Rights Information

Perhaps the most publicly known NGOs are those that focus on human rights and social justice issues. Some of the most prominent of these include Human Rights Watch, Amnesty International, and the Child Rights Information Network, which operate on an international basis. Human rights NGOs, particularly those that advocated for the abolition of slavery in the nineteenth century, are among the first documented NGOs after the advent of the current nation-state system. Currently, human rights NGOs focus on topics that range from state-initiated abuses of power to the cultural and economic aspects of human rights outlined in the UN Universal Declaration of Human Rights.

Unlike NGOs that focus on development or education, these groups often operate counter to official government policy and action. This complicates the ability of these organizations to collect and disseminate information, secure funding, and receive technical support. Often support to disseminate reports and research comes from international organizations and transnational communities. This unstable relationship between human rights NGOs and their host countries was quite visible in Uzbekistan in recent years when almost all NGOs with international support, including educational and developmental groups, were closed down.

The dangers faced by these NGOs and their workers affects researchers and librarians since the dissemination of documentation emanating from human rights NGOs can be difficult to verify and attribute. Additionally, primary source materials from these NGOs that become widely available have the potential to imperil those who work under repressive regimes and seek to work and cooperate with NGOs anonymously.

Following the flows of human rights information through NGOs provides a view of a vast and interconnected group of organizations that operate on local, national, regional, and international levels with the explicit goal of documenting and disseminating information related to human rights and related issues. In a sense, information flows from these organizations in an inverted pyramid as seen in Fig. 2, with local NGOs, researchers, and advocates pushing information upward in the system toward the larger organizations that in turn publicize, reuse, and consolidate information towards a worldwide audience that ranges from nations and intergovernmental bodies to the general public and researchers of social phenomena.

The data these NGOs rely upon in this stream consists of published and unpublished information. Many NGOs routinely collect published information from traditional

Fig. 2 Information flow—human rights.

print and electronic media, other NGOs, IGOs, and governmental sources to incorporate into reports, press releases, and handbills. Depending on the scope and scale of the NGO, these “collections” maintained by NGOs are on one extreme, collected, cataloged, and distributed electronically to staff throughout the world, such as the system employed by Amnesty International. At the other extreme, collections simply pileup in office corners without systematic processing or organization.

Unpublished information from these NGOs consists of the actual data or primary source material gathered from within a community or region by the NGO’s staff and researchers. This “data” can consist of anything from interviews with prisoners and witnesses of abuses to an accounting of local demographic information. This data is also integrated into research reports and other publications of the NGO. Like published collections within an NGO, this unique data is collected and archived based upon the scope and capacity of the organization. Unlike the published collection, these vast unique repositories of local and regional knowledge are largely inaccessible to outside researchers and organizations, and represent one of the least stable and inaccessible forms of grey literature.

Much of the current information pattern is heavily reliant on the growth of the Internet and availability of cellular- and satellite-based communications technologies. Information can be disseminated quickly and often synchronously to a large audience as violations occur, impacting greatly the potential to inform the public and promote remedial action. In addition, organizations once isolated are now networked to enable direct communications and collaboration. The 1984 Vallerti Agreement formed one of the first of these networks, linking aid and social justice organizations to worker organizations, activists, and effectively facilitating community-based research through the Interdoc network. This in turn led in 1990 to the Association for Progressive Communications’ online network and ultimately to Interdoc.^[10] The advent of the World Wide Web and open source technologies that allow

organizations to create online communities and groups has further provided organizations with access to the Internet, with the capacity to disseminate information and share expertise among social justice and human rights NGOs.

Internet technologies also provide the various publics of an NGO with a venue through which to access information. For example, the organization HURIDOCs maintains a search engine that provides access to documentation and materials from over 3000 Human Rights NGOs, effectively linking these groups and their potential impact to researchers and members of civil society around the world.

Human Rights NGOs also work to educate people about the concept of human rights as formally defined by the United Nations and legally defined within countries. Human Rights Education was catapulted into the mainstream when the UN made 1994–2004 the “Decade for Human Rights Education.” The UN’s focus on Human Rights Education, which continues today, provided NGOs with funding from organizations ranging from governments, UN bodies, and foundations such as Soros to educate and broadly disseminate human rights information to the general public, the legal community, and even military groups. Through these initiatives, many resources ranging from curricular materials to research on outcomes were developed throughout the world. Some of this is available through the Office of the United Nations High Commissioner for Human Rights though most is dispersed throughout the world’s NGO community.

It is evident that the Internet quickly became a tool for protecting and promoting human rights, but has also impacted upon traditional modes of information management within organizations, requiring organizations to allocate more resources towards technology and focus on information organization, metadata, and a notion of an audience broader than a local population or government. In most instances, NGOs have opted to emphasize technical infrastructure and Web-based resource development. Most NGOs, especially those that operate locally or regionally, do not employ information professionals or maintain and archive digital and print materials that are produced. Additionally, a formal library to collect and organize research materials, publications, and archival records is the exception rather than the norm among NGOs.^[11–13] This fact heightens the need for larger international NGOs to actively collect, organize, and archive materials from the local organizations. University libraries, research consortia, and associations can also potentially address these needs through collaborative digitization and archival programs.

Development and International Assistance NGOs

Development and international assistance NGOs work toward economic development within a country. In this context economic development includes activities aimed

at building a society's capacity to provide for the welfare of its people. Activities range from institution building, developing markets, educating farmers, and providing technical assistance and material resources among others.

Unlike many Human Rights NGOs, NGOs that work in development often partner directly and openly with their own and other governments plus international organizations such as the World Bank and the UN's Food and Agricultural Organization (FAO). This often presents to the public and general researcher a confusing network of governmental, nongovernmental, and quasigovernmental organizations that works with similar communities and often in partnership on the same program. For example, the U.S. Agency for International Development and FAO might simultaneously fund an NGO whose aim is to alleviate famine in Liberia.

The number of organizations that may work in a region to address a problem potentially causes much confusion and can inhibit the provision of aid. For example, the lack of information coordination was acutely visible in the aftermath of the South Asian Tsunami when multiple governments and aid organization sent resources and personnel to assist in recovery and redevelopment efforts.

The shape of information flow within the development community is more pyramid shaped, with knowledge and technical expertise moving from larger organizations such as governments, universities, IGOs, and large NGOs. This knowledge moves through a variety of conduits. Often knowledge transfer occurs through direct exchange and training. For example, an NGO that works in the area of water quality and access might receive support from a larger organization that funds university experts to consult with and train a local community in the development and maintenance of an efficient and sustainable water purification system. These experts from the academic community may also receive funding from various government research grants for their field work.

Technology and mobility have also contributed to providing access to knowledge and information. For example, Book Aid, a U.K.-based NGO, works directly with communities to select and disseminate books and other reading materials to set up lending libraries. On the technical side, JSTOR, initially an NGO funded by the Mellon Foundation and whose mission is to archive and provide wide access to prominent scholarly journals, initiated a program through which universities and nonprofit organizations in African countries are eligible for free access to the entire electronic collection.

As in the case of Human Rights NGOs, the Internet and similar technologies have allowed the structure of information flows to begin changing from one in which knowledge flowed mainly one direction to a growing structure through which NGOs increasingly have the capacity to share knowledge and expertise, creating a flow that may resemble more of a churning motion than linear trajectory.

Educational NGOs

Educational NGOs focus on a myriad of topics, ranging from human rights, as noted above, to health education, literacy, and ICT proficiency. These organizations constitute a subgroup in the development category, yet for the information society, many educational NGOs overlap heavily with services offered by libraries and information professionals.

ICT Education

Greater access to technology and the realization of the potential for knowledge and information to empower people and enhance capacity-building programs fuels the need for and expansion of ICT education programs within the NGO community. These programs include skill and technology development for NGOs and community-based projects to provide education on the use of ICTs to support everything from small business and entrepreneurs to virtual student exchanges.

For example, the International Institute for Communication and Development, a Dutch NGO, maintains multiple programs throughout Africa, Latin America, and the Caribbean to promote capacity building in ICT expertise and sharing knowledge among organizations across regions through networked-based technologies. In addition to capacity building, this NGO works closely with iEARN, an NGO that facilitates student exchanges and international friendships with a vast network of affiliated offices in nearly 120 countries. iEARN in turn collaborates and works with NGOs, IGOs, and governments around the globe, constituting another vast and churning network of information exchange and communication maintained by NGOs and facilitated by ICTs.

Literacy Education

Literacy education, including basic, computer, cultural, and economics is a major activity among NGOs in the developed and developing world. Many literacy programs, especially those that promote adult literacy and reading to children partner directly with public and school libraries and work in consultation with librarians and their associations. For example, Baby Talk, a U.S.-based NGO, operates its early reading intervention program within local public libraries and community centers. On an international level, the UN has denoted 2003–2012 as the Literacy Decade. Similar to the impact on human rights education, UN denotation has increased the level of funding for organizations involved in literacy education through both the UN and foundations from Carnegie to Starbucks.

Information Literacy is also an educational component within NGO literacy education. As noted by Jackman and Jones, information literacy is an essential piece in capacity building as individuals and organizations gain greater

access to information through open markets and greater access to technology.^[14] Libraries and information professionals are poised to provide information literacy training to NGOs at a time when these organizations are adopting ICTs and developing new systems to organize and disseminate knowledge. In addition, library-focused associations such as IFLA and the U.S.-based ACRL are dedicating increasing energy to information literacy education and dissemination of materials to assist librarians and other information professionals improve their education programs.

Library Professional Development

Library professional development programs are also widely funded and delivered by NGOs. The MacArthur, Mellon, and Carnegie foundations all fund programs to educate and train library leaders in both developing and more developed countries. The Mortenson Center for International Library Programs, which is housed at the University of Illinois at Urbana-Champaign, offers exchanges and training programs within the United States, Russia, and Africa through a combination of support from these foundations. Beyond foundations, some of the other major funders of library-related NGO programs include UNESCO, and numerous government-sponsored grant and development programs that focus on both national and international capacity building.

ACCESS TO KNOWLEDGE (A2K) MOVEMENT

The global A2K movement focuses simultaneously on human rights, ICTs, and education in an effort to advocate for access to knowledge. The movement is based on the premise that access to knowledge is central to the well-being of societies, communities, and individuals.^[15] A2K organizations work as both policy advocates and providers of direct assistance. NGOs in the A2K community directly support, and in many ways parallel, the work and missions of libraries through their advocacy, access, and educational missions.

A2K policy advocates focus on national and international policy such as copyright, accessibility standards, and technical protocols. One of the major campaigns of the movement is to reform the World Intellectual Property Organization (WIPO) to limit new treaties and standards that impede access to information while shifting WIPO's focus away from intellectual property protection toward an agenda that would promote knowledge creation and developmental assistance. The International Federation of Library Associations (IFLA) works closely with IGOs and NGOs in the A2K community, notably through their work with the UN's World Summit on the Information Society (WSIS).

As noted above, many NGOs provide developmental assistance in the form of access to information and training. These programs parallel and complement the A2K movement by virtue of work they promote and perform.

Electronic Information for Libraries (eIFL.net) works within this A2K community to support and advocate access to electronic resources by working with libraries in developing countries to negotiate affordable subscriptions and build capacity to develop, disseminate, and preserve locally produced knowledge.

Through policy work and development assistance, the A2K NGOs encompass the numerous legal, economic, and technical issues that library professionals in all nations face. These issues include digital copyright, privacy, data security, and advocacy for the profession and its global community of users.

NGO ARCHIVES AND COLLECTIONS

A variety of archives exist for nongovernmental organizations. These include true archives of all organizational papers and more loosely collected works by and about organizations. Some NGOs such as Oxfam recognize the importance of an information archive and have the resources to maintain their own archival materials. Others, with fewer resources or a briefer history, rely upon others to collect and preserve their materials.

For example, the University of Colorado at Boulder maintains archival materials from the American Friends Service and various other pacifist movements. On a more global basis, the Database of Archives of Non-Governmental Organizations (DANGO) is attempting to maintain an information archive of the activities of a large number of organizations in Great Britain that have been in existence since 1945. On the other side of the globe, the Center for the Study of Cooperative Human Relations at Saitama University in Japan houses a large collection of what is referred to as "Citizens Records" going back to the 1970s. This includes the publications of a large number of NGOs and grassroots organizations published both in Japan and elsewhere.^[16-18]

In addition to formal archives, some educational institutions support the dissemination of information to answer the questions that NGOs might have in various areas. A good example of this is the Women's Human Rights Resources Programme at the University of Toronto. The program has developed a database of resources to assist those working in the area of the legal rights of women in Canada and elsewhere that can be queried. This is ultimately what many NGOs strive to do—provide easily accessible information to a client base and beyond.^[19,20]

CONCLUSION—THE FUTURE OF GLOBAL CIVIL SOCIETY

The concept of global civil society as exemplified by the existence of NGOs will continue in importance in the future. The exponential growth of these organizations that

was witnessed in the last part of the twentieth century and the beginning of the twenty-first century will no doubt slow in the future. However, the organizations will always spring up where there is need for joint action, information dissemination, and a seat at the table of policy-makers. These are ultimately the purposes for which these organizations exist. If the organizations are true to their goals, they should hope they will fade from view as the problems and issues they highlight are addressed. In the meantime, it is likely that less-democratic countries will continue to challenge their work, especially those working in the area of human rights. More stable democratic regimes will no doubt attempt to make these organizations more accountable for both their actions and their finances. The library community needs to start now to capture the information production of these groups and assist organizations create and disseminate the information at the heart of all NGOs.

North American Serials Interest Group

Jill Emery

Portland State University Library, Portland, Oregon, U.S.A.

Abstract

The North American Serials Interest Group (NASIG) was founded in 1985 and hosted their first conference at Bryn Mawr College in 1986. NASIG is an independent organization that promotes dialogue and professional growth among all members of the serials information community. NASIG is a membership-driven organization that holds an annual conference to represent the diverse interests of the serials community.

INTRODUCTION

The North American Serials Interest Group (NASIG) was founded in 1985 after 16 American librarians attended the United Kingdom Serials Group (UKSG) Meeting in 1984 and began to discuss what it would take to create a similar organization in North America. Becky Lenzini, who was a librarian working for the Faxon Company, and John Riddick, a librarian working at Central Michigan University, started a study group to investigate the feasibility of a North American Serials Group. An ad hoc executive council was formed that included John Riddick and Becky Lenzini as cochairs, Tina Feick (Boley) as vice-chair, Susan Davis (SUNY-Buffalo) as treasurer, Marilyn Gonsiewsky (Cal Poly-San Luis Obispo) as secretary, and Lenire Wilkas as the first newsletter editor. Dues were initially set at U.S. \$15. Membership solicitation began and the first conference site, Bryn Mawr College, was selected. In addition, a site selection committee made up of John Riddick, George Lupone (Cleveland State University), and Tina Feick did site visits in Ohio to find the location for the second conference.

The first *NASIG Newsletter* appeared in January 1986. In the meantime, Leigh Chatterton from Boston College and Mary Beth Clack from Harvard were appointed to serve as the first conference program chairs. Denison University in Granville, Ohio, was selected as the site for the second conference. By May 1986, membership had grown to 324 members and draft bylaws for the organization had been distributed. In June 1986, the first conference took place and remains the highest ranking conference in the history of NASIG. The first elections took place in November of 1986 where the bylaws were approved by the membership and NASIG was well on its way.

NASIG's 10th anniversary conference was held at Duke University in 1995 and was a wonderful celebration of the organization's decade of history. Members recollected that while the organization has continued to grow, they maintained an enthusiasm and dedication to the

organization that has been unparalleled. NASIG's 20th anniversary was held in Minneapolis, Minnesota, in 2005. This celebration noted that NASIG continued to work on refining its function as an organization and the ongoing development of their governance. In 2010, NASIG celebrated its 25th anniversary in Palm Springs, California. Financial planning, membership development, and technological planning have become the main issues of the organization during its maturity.

Permanent archives for the organization were established in 2003 at the University of Illinois, and an archivist position was created to archive. Today, NASIG is a financially stable organization that holds a world-recognized annual conference in North America and continues to provide a forum that promotes the communication, understanding, and sharing of ideas among all members of the serials and electronic resource information community.

MEMBERSHIP

NASIG has continued to grow and prosper. Having reached a membership high of close to 1500 members in the early part of the millennium, NASIG now holds a steady membership of around 725 members. The membership dues have grown to keep up with the economic climate and currently are at U.S. \$75 for regular members and U.S. \$25 for retired and student members. In 2010, an organizational membership category was created and instituted. The rate for this membership category is U.S. \$1500. The organizational member rate allows for a dedicated table at the annual conference vendor exposition, recognition of the organization's membership on the NASIG website, and the ability to designate three individuals in the organization as NASIG members.

Personal membership benefits include access to the online membership directory, presenter's handouts from

the annual conference, and access to the *NASIG Proceedings* archive. In addition, members also receive the NISO (National Information Standards Organization) member rate for NISO webinars, reduced rates for the annual conference and webinars, and a discount subscription rate to *The Serials Librarian*. Lastly, members also get biweekly e-mails of *Serials E-News* from UKSG.

NASIG ORGANIZATIONAL STRUCTURE

NASIG has an executive board made up of the following positions: President, Vice-President/President-Elect, Past President, Secretary, Treasurer, six Members-at-Large, and ex officio member in the form of the *NASIG Newsletter* Editor-in-Chief. Each member of the executive committee serves as a direct liaison to NASIG's committees and task forces. The current committees are Awards and Recognition, Bylaws, Conference Planning, Continuing Education, Database and Directory, Electronic Communications, Evaluation and Assessment, Financial Development, Membership Development, Mentoring, Nominations and Elections, Program Planning, Publications and Public Relations, Site Selection, and Student Outreach. There is currently one task force, Core Competencies. In addition, there are individuals appointed to the positions of Archivist, Conference Coordinator, Conference Proceedings Editors, Newsletter Editor-in-Chief, and Registrar.

Each committee has a formal written charge from the Board, which is reviewed and modified as needed by the executive board. Any current NASIG member is eligible to serve on a committee and can indicate their preference for committee appointments by submitting a volunteer form. The vice-president/president-elect is responsible for all committee, task force, and board liaison appointments. In general, committee members are not allowed to serve more than two consecutive terms on any given committee.

AWARDS AND SCHOLARSHIPS

The greatest benefits that NASIG provides to the information community are the numerous awards the organization provides. Currently, there are eight awards sponsored by NASIG each year. The John F. Riddick student grant award is the oldest award offered by NASIG. The grant provides conference expenses and a one-year membership to current library and information science students. The grant was named after one of the cofounders and first elected presidents of NASIG, John F. Riddick. It was his idea to begin to offer student grant awards in 1988, and they have been successfully granted since the inception of the award. Many members of the NASIG student grant awards have gone on to become leaders in the library and information science field in addition to serving in

leadership roles in NASIG as committee chairs and on the executive board. To date, 162 student grants have been awarded and NASIG is recognized as a leading organization in the profession in fostering and mentoring new professionals.

The next oldest award is the Horizon Award, which was created to advance the profession by providing promising new information professionals with the opportunity to accelerate their knowledge and understanding of serials by networking and interacting with all members of the serials information environment from vendors to other librarians. This award is granted to professionals who have three or less years' experience in their serials-related position and have not previously attended the NASIG annual conference. To date, there have been 27 Horizon Award winners and many of those winners have gone on to serve as NASIG committee chairs and executive board members.

In 1998, NASIG awarded the first Fritz Schwartz Serials Education Scholarship. The scholarship is named in honor of Fritz Schwartz, who was a well-known and highly respected authority on Electronic Data Interchange (EDI), the Internet, and library standards. He was a frequent and well-received speaker at NASIG conferences. This award is open to qualified graduate-level students in any NASIG member country (Canada, Greenland, Mexico, or the United States) who demonstrate serials-related work experience and a desire to pursue a professional serials career after earning their degree. To date, 16 Fritz Schwartz Serials Education Scholarships have been granted. The winner is awarded a U.S. \$3000 scholarship as well as a student grant award to attend the NASIG conference for the year in which the scholarship is granted and a one-year free membership to the organization.

In 1999, the Marcia Tuttle International Grant Award was created to provide funding for an individual working in any area of the serials information chain to foster international communication and education through activities involving some aspect of serials. The award provides a U.S. \$3000 grant and a one-year free membership. This award is only given as qualifying applications are received, so there are years where this award is not granted. To date, eight awards have been made for research projects based in or working with China, Europe, Eastern Europe, and the Middle East.

Another premier award developed and offered solely by NASIG is the Mexican Student Grant Award. This award grants assistance to a Mexican student of library/information science to attend the annual conference and to receive a one-year free membership in the organization. This award was first created in 2001 and has been awarded almost every year since then with 11 recipients of the award to date. The Mexican students enjoy the recognition as well as the opportunity to participate in the national library conference event in the United States.

The Champion Award was created in 2005 in conjunction with the 20th anniversary of NASIG. The Champion Award is selectively given to members of NASIG who have a long history of dedicated service to the organization to honor their contributions both to NASIG and to the profession at large. To date, only two Champion Awards have been made, the first to Tina Feick, a founding member of NASIG and active member in the serials information chain. The second recipient, Susan Davis, is also a founding member of NASIG and has also been extremely active in the serials profession throughout her career. Both award winners served as President of NASIG at one point in their careers.

In 2006, NASIG created the Serials Specialist Award in order to provide conference travel funding for a promising paraprofessional working with serials to advance their knowledge and understanding of serials work. Along with the travel stipend, the award winner also gains a year's free membership to NASIG. There have been eight recipients of the serials specialist award to date.

The Rose Robischon Scholarship Award was created in 2009 to honor NASIG member Rose Robischon who had two decades of service to NASIG. She served as a chair on numerous committees and was the NASIG Treasurer from 2005 to 2007. The scholarship provides the recipient with funding to attend the annual conference in the year that it is awarded. The award is open to any NASIG member who currently holds a position where their primary responsibilities cover some form of serials management or enterprise and for whom travel to the conference cannot be covered by their employing institution or organization. Preference is given to applicants who have not been able to previously attend NASIG and who can show a benefit in their application for attending the conference. To date, there have been four award winners for this scholarship.

The most recent award is one that was developed in conjunction with UKSG. The award is named in honor of John Merriman in recognition of the role he played both in UKSG and with the development of NASIG. John was the conference organizer of UKSG and was the person who extended an invitation to 16 American serial librarians in 1984, which led to the creation of NASIG. The John Merriman Joint NASIG/UKSG Award pays for one UKSG member to travel to the NASIG conference each year and for one NASIG member to travel to the UKSG conference. The award is open to any member of each organization and consists of travel expenses up to U.S. \$3000 for the attendance at the other conference but does not cover the expense of attending the local conference. Current board members of either organization are not eligible for the award. The committee vetting the award is made up of members from both organizations. To date, six members of NASIG/UKSG have been able to experience each other's conference and learn how serials are managed in different areas of the world.

CONTINUING EDUCATION

NASIG sees the need for finding ways to better support the ongoing educational needs of its members and the serials community. In addition to the annual conference, NASIG has sponsored local and regional continuing education activities such as the North Carolina Serials Conference and the Ohio Valley Group of Technical Services Librarians annual meeting as well as numerous CONSER and Serials Cataloging Cooperative Training Programs offered by the Library of Congress. In 2012, NASIG began offering a quarterly webinar series including sessions on open-source integrated library systems, library use of publisher metadata, and effective negotiation. NASIG has also partnered with the NISO allowing NASIG members to register for NISO continuing education events at a discounted rate. This has been a well-utilized partnership for NASIG and NISO.

PARTNERSHIPS & OTHER OUTREACH

In addition to UKSG, the Library of Congress, and NISO, NASIG has sought to forge partnerships with other relevant organizations. Most specifically, in 2009, NASIG entered into an information sharing agreement with the Association for Subscription Agents and Intermediaries to help promote events of both organizations. As part of its student outreach efforts, NASIG established the Student Ambassador's Program, which links NASIG members with North American library and information science programs. The presentations that NASIG ambassadors give to LIS students are often the first time that a student has heard of the organization or become aware of that specialization in the profession.

NASIG PUBLICATIONS

NASIG has two primary publications that it produces on a regular basis. The first is the *NASIG Newsletter*, which is produced quarterly each year and covers the business and membership news and information. The newsletter is expanded upon with the use of the *NASIG Blog*, which is updated four to six times a month. Begun in 1986, the newsletter with the inception of the organization has been produced regularly since then. In the early 2000s, the *NASIG Newsletter* moved online and is now produced entirely electronically. Certain segments such as the President's Corner, conference reports, and member updates have been an integral part of the newsletter since its inception. All issues of the *NASIG Newsletter* are freely available here: http://www.nasig.org/publications_newsletter.cfm.

In addition to the *NASIG Newsletter*, the *NASIG Conference Proceedings* have also been produced since the

inception of the organization. The conference proceedings fully encapsulate the scholarship and presentations given each year at the annual conference. The *NASIG Conference Proceedings* appear each year in *The Serials Librarian*, and NASIG and the publishers of *The Serials Librarian* have enjoyed a joint partnership in bringing this area of knowledge and expertise for 27 years. An electronic version of all of the conference proceedings are made available on the NASIG website to NASIG members. The *NASIG Conference Proceedings* are highly cited works, and it is to the organization's credit that this level of scholarship is brought to publication each year.

NASIG has recently developed a statement of *Core Competencies for Electronic Resource Librarians*. As an emerging area of the profession, this document has become a useful publication for students, early career professionals, and employers who wish to describe these specialized positions and the criteria upon which to evaluate the performance of those who hold them.

ANNUAL CONFERENCE

The annual NASIG conference is considered the go-to event for technical services librarians and collection management librarians involved in the selection and management of ongoing subscription services and more recently the management of electronic resources. The conference brings together a mix of librarians, publishers, intermediaries, and service providers in one event for concentrated programs on serials and electronic resource management. Initially, the conference was held on universities with the attendees staying in campus dorm rooms during the intercession periods for the university/college. This dictated the annual conference occurring during May and/or June each year between spring and summer terms. Over the years, as colleges campuses began to charge more and the meeting became more popular, it was found that hotel conference centers were often competitive in both amenities and location. For this reason, NASIG's membership voted in 2013 to move the conference from the university setting to the hotel environment. The conference has remained in the May/June time frame since long-term members and attendees have come to expect the conference being held in this time frame.

The location of the annual conference varies each year to allow for attendance by local members and others within the library and information science community who may otherwise not get to travel to conferences.

The conference typically runs for four days and usually occurs over a weekend. The first day of the conference includes preconferences that are additional cost to the main registration and provide in-depth exploration of various topics. In the evening of the first day is the opening

reception and welcome to the location from the conference planners and local members of the community. The second and third days are full conference days with plenary sessions kicking off the conference each day followed by breakout sessions that attendees can choose from to attend. In addition, there are usually lunch breaks provided that allows plenty of time for networking and joining up with colleagues. There are usually evening opportunities presented as well for attendees, and NASIG has a long tradition of trying to pick locations with either minor or major league baseball games occurring for blocks of members/attendees to attend as well. The last day of the conference is usually a half day to allow for travel arrangements. In addition to programmed events, there are committee meetings, a members' business meeting/town hall event, as well as various networking opportunities that focus on the use of specific management tools or products.

In 2010, NASIG instituted a vendor showcase for vendors and publishers to have an opportunity for a dedicated "sales" time period. This is usually held prior to the opening session on the first day, and attendees/members have an opportunity to interact with their friends and colleagues on a business level prior to the conference beginning. This event was seen as controversial for some NASIG members since the intent of the annual conference was meant as meeting of the minds from all areas of the serials and continuing resources community and not a sales event. However, the past few years have shown that having this minor business opportunity upfront has benefitted both the corporate institutions involved with NASIG as well as providing the librarians to explore products and content they might not otherwise know.

CONCLUSION

NASIG has been and continues to be a vital organization in the library and information profession. It provides opportunities for new librarians and information specialists to become professionally active and participate in an environment that is nurturing and engaged in many activities from publishing, to attendance at the annual conference, to committee work. NASIG offers multiple opportunities for engagement and for forging a sense of community who may otherwise become lost in larger professional organizations such as the American Library Association and its myriad of divisions and committees. NASIG was founded with the ideology that would remain an independent organization that promotes dialogue and professional growth among all members of the serials information community. NASIG has not only succeeded in this vision but continues to prosper upholding the principles its founders developed 27 years ago.

OCLC: A Worldwide Library Cooperative

Jay Jordan

OCLC Online Computer Library Center, Inc., Dublin, Ohio, U.S.A.

Abstract

This entry describes the history, governance, and current activities and plans of OCLC Online Computer Library Center, a nonprofit, membership, computer library service, and research organization dedicated to the public purposes of furthering access to the world's information and reducing library costs. OCLC and its member libraries cooperatively produce and maintain WorldCat—the OCLC Online Union Catalog.

INTRODUCTION

OCLC, Online Computer Library Center is a nonprofit, membership, computer library service, and research organization. Since its founding in 1967 by university presidents in Ohio, OCLC's mission has been to further access to the world's information and reduce library costs. At this writing, more than 69,000 libraries participate in a worldwide cooperative that extends to 112 countries. Libraries use OCLC services to help manage their collections and provide reference services to end-users.

OCLC has approximately 1200 employees, with some 860 on its main campus in Dublin, Ohio. In the United States, OCLC has offices in California, Colorado, Kansas, New Jersey, Pennsylvania, Washington state, and Washington, DC. There are also 16 offices in these countries: Australia, Canada, China, France, Germany, Mexico, the Netherlands, Switzerland, and the United Kingdom (Fig. 1).

HISTORY

Founded in 1967 by librarian Frederick G. Kilgour and the Ohio College Association (a group comprising the presidents of Ohio's private and public colleges and universities), OCLC was originally called the Ohio College Library Center. In 1971, OCLC pioneered the digital revolution in libraries with the introduction of its first service, the Online Union Catalog (today called WorldCat) and Shared Cataloging System. Since then, enormous changes in computer technology and telecommunications have occurred. The original terminals, computers, and telecommunications network have given way to several succeeding generations of technology, each of which has been faster, better, cheaper, and smaller than its predecessor.

The advent of the Internet in the mid-1990s, and then the World Wide Web, caused a sea change for libraries and librarianship. The sheer volume of electronic information, coupled with the emergence of search engines that

appeared to offer viable alternatives to library services, presented libraries with new challenges.

OCLC enters the twenty-first century and its fourth decade with services and strategies that are intended to help libraries not only cope, but thrive, in an environment of continuous change. To that end, OCLC at this writing was pursuing two strategic objectives: 1) to weave libraries into the World Wide Web and the Web into libraries and 2) to extend the cooperative to provide more value to more libraries around the world.

GOVERNANCE

OCLC's governance has always been closely intertwined with the use of OCLC services and the growth of WorldCat, the OCLC Online Union Catalog. Membership is based on the use of OCLC services and contribution to the OCLC cooperative.

From 1967 to 1977, membership in OCLC was limited to institutions in Ohio and governance of OCLC resided in a nine-member board of trustees elected by Ohio member institutions of the Ohio College Library Center. In 1977, the Ohio membership relinquished control of OCLC and established a governance structure that extended membership to libraries and other institutions outside Ohio. The governance structure that was implemented in 1978 consisted of three parts: Members, Users Council, and Board of Trustees. This structure provides libraries with an institutionalized role in governing the cooperative whereby members elected Members Council delegates, who in turn elected six members of the 15-member OCLC Board of Trustees.

In 2002, the governance structure was modified to complement new services, increased international activity, and new forms of contribution. The name of Users Council was changed to Members Council. The Board and Members Council broadened the definition of "contribution," which since 1978 had included current cataloging and holdings information. Contribution was defined as

OCLC's Chartered Objectives

As set forth in OCLC's Articles of Incorporation, the objectives of OCLC are to "establish, maintain and operate a computerized library network and to promote the evolution of library use, of libraries themselves, and of librarianship, and to provide processes and products for the benefit of library users and libraries, including such objectives as increasing availability of library resources to individual library patrons and reducing rate-of-rise of library per-unit costs, all for the fundamental public purpose of furthering ease of access to and use of the ever-expanding body of worldwide scientific, library and educational knowledge and information."

Fig. 1 OCLC charter.

"intellectual resources provided and shared by libraries and other institutions through the products and services of OCLC and its affiliates for the benefit of other members of the cooperative."

There were three levels of membership participation: Governing Members, Members and Participants. Governing members were institutions that contractually agree to contribute metadata to WorldCat, including all current cataloging and holdings as described in the "OCLC WorldCat Principles of Cooperation," and to make the information available for the benefit of all participants in the OCLC cooperative. Governing members received credits from OCLC for their contributions to WorldCat and received a discount on OCLC services. Governing members elected delegates to the OCLC Members Council, which in turn elects six members of the Board of Trustees.

Members, like governing members, embraced the OCLC values of commitment to collaboration by contributing intellectual content and by sharing resources. While they were not contractually bound to contribute all of their current cataloging to WorldCat, they did contract to contribute to cooperative products or services provided by OCLC and its affiliates. They also received a discount on OCLC services. Representatives from member institutions were eligible for election to Members Council and the Board of Trustees.

Participants contracted to use OCLC products and services without any obligation to return any intellectual content to the cooperative. While participants did not have a direct vote in the affairs of the cooperative, they are encouraged to provide input to their networks, service centers, and Members Council delegates.

The second part of the governance structure was the Members Council, which provided a formal institutional means for the governing members to participate in election of trustees and policy decisions. The OCLC Members Council consisted of 66 delegates who met three times a year. Elections were conducted by OCLC-affiliated networks and regional service centers in the United States and around the world.

Members Council delegates had three main responsibilities: 1) to elect six delegate librarians to the OCLC Board of Trustees; 2) to ratify amendments to the OCLC Articles of Incorporation and Code of Regulations; and 3) to provide advice and counsel to

OCLC. The number of delegates each network or service center may elect is based on a formula that takes into account service revenues in cataloging and resource sharing.

A typical Members Council meeting took 2.5 days. The meeting was organized along an annual theme adopted by the delegates. In 2006–2007, the theme was "OCLC Organizational Dissonance: The New Harmony." On February 5–7, 2007, delegates for the first time met outside the United States in Quebec City, Quebec, Canada.

Much of the work (the providing of advice and counsel to OCLC) of the Council was done in small groups that are asked to address specific questions and issues. These groups were organized along service areas, such as cataloging and metadata, digital libraries and research, global librarianship, cooperative reference and preservation/electronic collections, and resource sharing. Additional groups were organized by library type: systems and state libraries; government and special libraries; research libraries; public libraries; private academic libraries; and state academic libraries. These groups produced minutes, which were forwarded to the Members Council Executive Committee. This activity resulted in a written report of significant issues that is sent to OCLC management for comment and possible action and feedback to the Council. This communication, both formal and informal, helped the OCLC cooperative stay in close touch with its member libraries and constituents.

The third part of the governance structure was the Board of Trustees, which was composed of six trustees elected by the Members Council, five trustees elected by the Board itself from fields outside librarianship such as law, finance, government and business, and three board-elected trustees from the general library community. The President of OCLC is an ex-officio trustee. The Board sets strategic goals and policy, approves plans and programs for achieving those goals, hires and evaluates the chief executive officer, approves annual budgets, oversees audits and other reports pertaining to the financial condition of OCLC.

Membership and participation in OCLC continues to become more global. Revenues from international operations in fiscal 2008 were \$56.2 million, which was about 23% of total revenues of \$246.4 million. That compares with 9.3% of revenues in fiscal 2000. In the past 10 years,

the number of libraries participating in OCLC outside the United States has increased from 6000 to almost 14,627 and the number of countries from 75 to 112. In 2007–2008, there were 17 Members Council delegates elected from outside the United States.

In 2007, the OCLC Board of Trustees recognized that as OCLC was becoming an increasingly global cooperative, its governance must be adjusted to ensure representation and participation by members around the world and conducted another periodic review of OCLC's governance. In 2008, the membership adopted a new governance structure for the OCLC cooperative. The new structure is designed to extend participation in the OCLC cooperative to an increasing number of libraries and cultural heritage institutions around the world. It includes regional councils that send delegates to a Global Council, which in turn elects six members of a 15-member Board of Trustees. The transition to the new structure was under way in 2009 and was coordinated by representatives of the 2008/2009 Members Council and the Board of Trustees. In 2009, regional councils were established in the Americas region, the Asia Pacific region, and Europe, the Middle East and Africa, with the first Global Council meeting set for 2010.

FINANCES

Throughout OCLC's history, the organization has funded its operations and paid for research and development with revenues generated by services provided to member libraries. OCLC does not rely on government appropriations, foundation funding, or membership assessments. OCLC's financial philosophy can best be summed up by the introduction to the financial section of the fiscal 2008 annual report reads:

OCLC is a nonprofit, membership, computer library service, and research organization whose public purposes of furthering access to the world's information and reducing library costs dominate its plans and activities. In support of these purposes, OCLC strives to maintain a strong financial base by operating in a business-like manner in order to accommodate growth, upgrade technological platforms, conduct research and development and still subsidize worthwhile projects for the benefit of libraries and their users. OCLC follows a conservative, nonaggressive accounting and operating philosophy in maintaining its financial reporting and internal control systems."^[1] (OCLC 2007/2008 Annual Report, p. 50)

OCLC WORLDCAT

At the heart of the OCLC cooperative is the WorldCat bibliographic database, which member libraries and

OCLC cooperatively produce and maintain. WorldCat is the world's largest Online Union Catalog, and among the most consulted databases in higher education. Each WorldCat record contains a bibliographic description of a single item and a list of institutions that hold the item. Institutions share these records, using them to create local catalogs, arrange interlibrary loans, and conduct reference work. Institutions contribute records for items not found in WorldCat using the OCLC shared cataloging system.

Since 1971, more than 130 million records have been added to WorldCat. These records describe materials that span five millennia of recorded knowledge, from approximately 3400 B.C. to the present. Records are in eight formats: books, continuing resources (serials), sound recordings, musical scores, maps, visual materials, mixed materials, and computer files. A member institution adds a new record to WorldCat every 10 sec.

WorldCat has become a unique library resource that is consulted by librarians and library users around the world. It is the result of the concept of shared cooperative cataloging, advanced by OCLC's founder and first president, Frederick G. Kilgour. Shared cataloging not only increased the productivity of library staffs, it also increased the availability of information for library users.

Using the OCLC cataloging system, a cataloger searched the database for a bibliographic record for the item being cataloged. If a record was found, the cataloger used it for the library's catalog. If no record was found, the cataloger created a new record and input it into WorldCat. Thus, shared cataloging made it possible for only one library to create an original catalog record for an item and then provide a means for other libraries to use that same record for their catalogs.

Today, libraries find records they can use for current cataloging 94.6% of the time. Thus, for every 100 books cataloged, only about six required original cataloging. It is possible to catalog up to 14 titles an hour when records are resident in WorldCat, compared with two to three an hour when an original cataloging record must be created.

The ability to edit records and add information in real time meant that contributors could see cataloging results immediately, and any member library connected to the system could use the new information right away. Economies of scale increased as the number of records in the database and number of users grew.

Through WorldCat, OCLC has provided libraries with over \$1 billion in services based on cooperative cataloging and resource sharing. These services have not only been at low cost, but have saved libraries billions of dollars in potential duplicate costs. Today, libraries use WorldCat to help them select, order, catalog and get materials ready for shelves, and arrange interlibrary loans. WorldCat is now available to people everywhere on the Internet through WorldCat.org (see below). WorldCat is also available to library users as a reference database

OCLC Worldcat statistics by format
June 30, 2007

Type of material	Number of records	Percentage of total	Locations on LC records	Locations on participating	Locations on member-input	Location of items cataloged

through the OCLC FirstSearch service. The continuing evolution of WorldCat is discussed later in this entry (Fig. 2).

WORLDCAT ENRICHMENT AND QUALITY CONTROL

OCLC member libraries and OCLC maintain a proactive and rigorous quality control program that includes cooperative efforts at the national and international levels. To ensure the quality of WorldCat, all participating libraries are required to comply with specified cataloging standards. The quality control program includes both manual correction of records or elimination of duplicates by OCLC staff and selected participating libraries and automated software that corrects headings and other items automatically.

In the Enhance Program, specially authorized users may lock and replace most full-level member-input bibliographic records in WorldCat, including national-level records. Through the Cataloging in Publication (CIP) Upgrade Program, OCLC works with materials vendors to accelerate the upgrading of CIP records in WorldCat and provide libraries with full cataloging records as soon as possible after publication. A number of OCLC member libraries and OCLC participate in the Program for Cooperative Cataloging (PCC), an international cooperative effort coordinated by the Library of Congress and aimed at expanding access to library collections by providing useful, timely and cost-effective cataloging. As part of the PCC, WorldCat is the host database for the CONSER (Cooperative Online Serials) program in which libraries and publishers build and maintain a comprehensive

database of authoritative bibliographic information for serials. OCLC also employs automated techniques in maintaining the quality of WorldCat records.

OCLC member libraries have been able to upgrade minimal-level records and add information, such as call numbers and subject headings, to many of the records in WorldCat. However, major changes to many records have been restricted to participants in the Enhance Program. In response to requests from the cataloging community, in 2009, OCLC started the Expert Community Experiment, in which OCLC libraries with full-level cataloging authorizations were able to improve and upgrade many more WorldCat master bibliographic records. The experiment was expected to result in more corrections and additions to master bibliographic records and more timely actions to correct record problems. The experiment was inspired by long-standing requests from members to be able to do more—and more immediate—upgrading of WorldCat records. The experiment also allowed OCLC to test a “social cataloging” model involving the existing community of cataloging experts who have built WorldCat record-by-record over the past four decades. Interest in such an experiment had grown with the launch of WorldCat Local and with the popularity of other socially cooperative ventures, such as Wikipedia.

In 2008, OCLC began the Next Generation Cataloging and Metadata service pilot, which explored the viability of capturing ONIX metadata upstream from publishers and vendors and enhancing that metadata in WorldCat. A variety of academic and public libraries, publishers, and vendors are participating in the pilot. In 2009, OCLC was preparing to publish case studies and findings from the pilot and to routinely ingest, create, and enhance metadata in WorldCat and output enhanced data in MARC and

ONIX. The start of the pilot last year coincided with the recent release of a "Report on the Future of Bibliographic Control" by the Working Group on the Future of Bibliographic Control, which was formed by the Library of Congress to address changes in how libraries must do their work in the digital information era.

WORLDCAT AND INFORMATION STANDARDS

WorldCat is based on MARC ("Machine-Readable Cataloging"—a format for communication of bibliographic information in machine-readable form developed at the Library of Congress in 1967) and *Anglo American Cataloging Rules* 2nd Edition. MARC21, the current format, represents a harmonization of U.S. and Canadian MARC. There are other MARC formats, such as U.K. MARC and UNIMARC, which is intended to be a global MARC standard.

In the 1990s, the Internet and then the World Wide Web changed the nature of publishing and information seeking. Cataloging information evolved into metadata, and the library community (AACR2/MARC) was not the only group creating and distributing metadata about electronic resources. In 1991, the OCLC Office of Research began studying Internet resources and their potential impact on library operations. In 1995, the National Center for Supercomputing Applications (NSCA) and OCLC held a workshop in Dublin, Ohio to discuss metadata semantics. The result was the Dublin Core, a 15-element metadata set intended to be interoperable and also allowing for author-generated description. In 2001, the American National Standards Institute approved the Dublin Core as NISO Z39.85-2001, and in 2003 it became an ISO standard (ISO 15836). In 1999, WorldCat began supporting Dublin Core as well as MARC21/AACR2.

OCLC was the host for the Dublin Core from its founding in 1995–2005, when it became a public, not-for-profit Company based in Singapore. The founding members of the new legal entity were the National Library Board Singapore and the National Library of Finland.

EVOLUTION OF WORLDCAT

Since 1971, OCLC had built and maintained WorldCat on its own proprietary system that it had developed in-house and continuously modified and updated. From 2001 to 2005, OCLC was engaged in a major project to move WorldCat to a new platform based on hardware and licensed software with widespread industry adoption. This was an important step in OCLC's strategy to evolve WorldCat beyond bibliography into a globally networked, Web-based information resource that would also provide links to digital objects in other knowledge repositories. The switch from a monolithic legacy system to hardware and licensed software with widespread industry adoption

enabled OCLC to develop new component applications based on open architectural models that provide improved interoperability within OCLC services and also with external services.

The new WorldCat platform supports additional standards such as Dublin Core and IFLA (International Federation of Library Associations and Institutions) standards for bibliographic records and Unicode, a character coding system designed to support the worldwide interchange, processing, and display of written texts of the diverse languages of the world. In 2007, WorldCat supported the following scripts for cataloging: Arabic, Bengali, Chinese, Cyrillic, Devanagari, Greek, Hebrew, Japanese, Korean, Latin, Tamil, and Thai. OCLC has also moved beyond bibliography to enrich WorldCat with new types of metadata and content such as book cover images, summaries, authors' notes and reviews.

GROWTH OF WORLDCAT

WorldCat has grown continuously since it began operation on August 26, 1971. In 2002, the number of records in WorldCat reached the 50 million after 31 years of shared cataloging. Libraries added the next 50 million records in just 6 years, with the 100 millionth record attained in 2008. The number of holding symbols in WorldCat reached 1 billion in 2005, and by 2009 had climbed to 1.4 billion. This growth is attributable to improvements in automated, batchloading processes and to the new technological platform with its Unicode capabilities that support 12 language scripts noted above, which makes it practicable for an increasing number of international organizations to merge their national union catalogs or other large files with WorldCat.

OCLC was also working to make it easier for national libraries and others to keep their union catalogs in synch with WorldCat. In 2008, the Dutch Union Catalogue started updating WorldCat in real time using SRU technology. In 2009, WorldCat's second SRU record update implementation began operation with Libraries Australia. Records appearing in the Australian National Bibliographic Utility now show up 5 second later in WorldCat. This machine-to-machine process is definitely introducing system-wide efficiencies that benefit the entire cooperative.

It is interesting to note that the language composition of WorldCat has changed over the past decade, with the percentage of records in languages other than English going from 38% in 1998 to slightly over 50% in 2008 (Fig. 3).

CATALOGING

In 2002, OCLC launched the Connexion cataloging service on a new technological platform. It combined functionality from existing OCLC services such as CORC,

Fig. 3 Languages in WorldCat.

Source: OCLC.

CatExpress, the Cataloging Micro Enhancer, Passport, and WebDewey. Connexion supports cataloging of all materials and formats from a single interface that the library can customize. It provides access to WorldCat, linked authority control, automatic classification, and the ability to build subject guides.

OCLC metadata and cataloging services are designed to help libraries manage their collections and increase the speed at which materials are made available for patron use. In addition to the online shared cataloging service described above, OCLC provides batch processing and Web-based cataloging systems that libraries use to catalog materials and maintain information on their physical and electronic collections.

These services include: automatic delivery of cataloging information with new books received from book vendors; automatic upgrading of cataloging records; workstation software that can be used on the cataloging system to automate certain cataloging tasks; cataloging system for Chinese, Japanese, and Korean (“CJKTM”) library materials; cataloging software for Arabic library materials; a Web-based copy cataloging system for small libraries with low volumes of cataloging (CatExpress); an authority control service; online, batch and microcomputer-based retrospective conversion services to convert older library cataloging records, usually cards, to machine-readable form; contract cataloging and processing service that acquires, catalogs and adds necessary labels to library materials, including

videos, DVDs, and CDs as well as books; and a terminologies service.

The oldest OCLC metadata service is the Dewey Decimal Classification (DDC) system, created by Melvil Dewey and first published in 1876. He established Forest Press in 1911 to edit, publish, and distribute the classification. In 1988, OCLC was asked to assume control of Forest Press. Subsequently, OCLC has published 20th, 21st, and 22nd editions of the DDC, 12th, 13th, and 14th abridged editions, and three electronic versions. The DDC has been translated into 30 languages and is used by over 200,000 libraries in 135 countries. Editing of the DDC is done at the Library of Congress. The DDC is available in both print and electronic versions.

In 2007, OCLC introduced a terminologies service, which provides access to multiple controlled vocabularies to enable creation of consistent metadata for library, museum, or archive collections. The vocabularies include: the Dublin Core; the Art & Architecture Thesaurus of the Getty Vocabulary Program, which describes objects of art as well as the processes and materials from which the objects are made; Newspaper Genre List from the University of Washington, Māori Subject Headings/Ngā Ūpoko Tukutuku from the National Library of New Zealand; and Thesauri for Graphic Materials I and II from the Library of Congress. One goal of the terminologies service is to make it easier for museums and archives to participate in the OCLC cooperative.

WORLDCAT COLLECTION ANALYSIS

Launched in 2005, WorldCat Collection Analysis provides data mining and manipulation capabilities that enable libraries to determine subject coverage in their collections and compare their collections with peer libraries to identify titles held in common and gaps in their collections. The service now includes: peer library comparisons, analysis of library collection and comparison to all holdings in WorldCat, and interlibrary loan analysis, which enables OCLC Resource Sharing users to determine how their collections are being used by others, as well as how they are supplementing their collections via interlibrary loan. Future developments include analysis of circulation usage statistics.

WORLDCAT SELECTION

In December 2006, OCLC introduced the WorldCat Selection service, which is based on ITSO CUL (Integrated Tool for Selection and Ordering at Cornell University Library). The service allows selectors of library materials to view new title data from multiple vendors in a single system. Acquisitions staff export selected records to load into the ILS to complete the ordering process. Staff can share selection decisions with others in their institution. The system streamlines selection, saves time and costs, and requires no software to load. The service now has these library materials vendors as partners—Aux Amateurs de Livres, Blackwell, Casalini libri, China National Publishing Industry Trading Corporation, Coutts, Erasmus, Howard Karno Books, Harrassowitz, Leila Books, Lindsay & Croft, Touzot, and YBP Library Services.

eSERIALS HOLDINGS SERVICE

In 2006, OCLC launched the eSerials Holdings Service, which helps libraries manage their eSerials collections. It automatically sets and updates WorldCat holdings for ISSN-based electronic serials each month. OCLC currently partners with EBSCO, OCLC Openly IGate, Serials Solutions, and TDNet on this service. About 1.8 million holdings have been set automatically in the past year. This service helps lower costs and increase the visibility of a library's eSerials collection to searchers and ILL librarians via FirstSearch, Resource Sharing, and Open WorldCat.

REFERENCE AND RESOURCE SHARING

OCLC's reference and resource sharing services build on and strengthen the tradition of interlibrary cooperation. OCLC introduced its online interlibrary loan service in

1979, and its online end-user reference service, FirstSearch, in 1991. Since then, the two services have become closely connected, based on the notion that searching, retrieval and delivery of information should be merged into a single, integrated service that would provide information to the user when and where needed.

The interlibrary loan service enables libraries to select holdings information electronically from WorldCat and to send requests for materials to other libraries in the OCLC network. For the year ended June 30, 2008, libraries conducted 10 million interlibrary loans online through OCLC.

The direction of resource sharing could be seen in OCLC ILLiad software that integrated borrowing automation, lending automation and electronic document delivery into one Web-based customer interface. Library users could easily send and track requests electronically through the Web while the system automatically processed filled requests and contacted users when requests were completed.

In 2009, OCLC further refined its consortial borrowing service with the introduction of WorldCat Navigator. The service manages returnable and nonreturnable items, and integrates with circulation systems to create a discovery-to-delivery tool.

QUESTIONPOINT

In 2002, with the Library of Congress, OCLC introduced QuestionPoint, a virtual reference desk collaborative service that includes e-mail, phone, walk-up, and fax capabilities. In 2004, OCLC acquired the assets of the 24/7 cooperative reference service project of the Metropolitan Cooperative Library System, Los Angeles, California, which enables library users to ask questions and get answers from qualified reference staff in real time on the Internet. In 2009, more than 1900 libraries were using QuestionPoint in 23 countries, and more than 1500 libraries were participating in the 24/7 reference cooperative, including 13 statewide services, the nationwide enquire service in the United Kingdom, and an additional 15 major regional services. The service handled questions in 26 languages. In 2008, the three-millionth reference question was logged on the service.

QuestionPoint uses the expertise of librarians to provide answers to questions, research guidance, and help navigating the Internet. Libraries may brand their own customized versions of QuestionPoint. For example, the Netherlands Public Library Association has customized QuestionPoint into Al@adin, a Web-based network of librarians in 50 libraries that delivers reference assistance to any library user in the country. Al@adin answers questions locally and nationally and can seamlessly refer them to other QuestionPoint users around the world. QuestionPoint subscribers maintain a Global Knowledge Base, which contains 18,000 records in 10 languages. In

2008, a chat widget was introduced that give libraries the ability to embed a snippet of HTML code throughout their Web pages and in a variety of environments, thereby providing access to the QuestionPoint service.

eCONTENT

Initially, OCLC services were designed for use by librarians to help manage their collections. When the FirstSearch service was launched in 1991, it was the first end-user reference system in the library community. Indeed, FirstSearch was in some respects as revolutionary in its early days, before the advent of the Web and search engines, as online shared cataloging had been 25 years earlier. Before FirstSearch and its user-friendly, menu-driven interface, online database searching was the exclusive preserve of reference librarians who alone knew how to devise search strategies to navigate complex and expensive databases. The library community rapidly adopted FirstSearch.

In use in more than 22,000 libraries, FirstSearch provides library end-users with desktop access to bibliographic, abstract, and full-text information from approximately 84 databases. It also provides document delivery of print and electronic materials and permits library users to request interlibrary loans. In the year ended June 30, 2008, there were 79.7 million searches conducted on FirstSearch.

OCLC FirstSearch Electronic Collections Online (ECO) provides cross-journal searching and access to electronic versions of 5600 journals and over 2.2 million full-text articles from 70 publishers. Accessible as a database on FirstSearch, ECO enables libraries to assemble, circulate, manage, and archive large collections of academic and professional journals on the World Wide Web. ECO provides links to other databases, WorldCat holdings information, and access to the OCLC interlibrary loan service. Libraries could also obtain bibliographic records that matched their journal subscriptions in order to facilitate access to the collection from the library's online public access catalog (OPAC).

In addition to WorldCat, OCLC produces eight databases that are available on FirstSearch:

- OCLC Union Lists of Periodicals includes more than 7 million location listings of local information linked to over 750,000 bibliographic records for periodicals WorldCat.
- OCLC ArticleFirst (15 million records) includes bibliographic citations from over 12,600 serials, covering science, technology, medicine, social science, business, the humanities, and popular culture.
- Electronic books include 675,000 records for online electronic books cataloged by OCLC member libraries.
- OCLC ECO provides cross-journal searching and access to electronic versions of 5600 journals and over 4.2 million full-text articles.

- OCLC PapersFirst (6.9 million records) gives access to individual papers presented at every congress, symposium, exposition, workshop, and meeting added to The British Library Document Supply Centre since October 1993.
- OCLC ProceedingsFirst (192,000 records) provides tables of contents of presented papers from conferences worldwide.
- OCLC WorldCat Dissertations and Theses (8 million records) provides access to the dissertations and theses available in OCLC member libraries.
- CAMIO (Catalog of Art Museum Images Online) provides more than 95,000 high-quality art images from prominent museums around the world.
- ArchiveGrid provides access to nearly 1 million descriptions of archival collections held by thousands of libraries, museums, historical societies, and archives worldwide.
- OAster provides access to 19 million records pointing to open archive collections, contributed by over 1000 organizations worldwide.

In July 2009, OCLC planned to make available all of its eContent resources through a single discovery platform—WorldCat.org. (see below). It will provide libraries with a single and familiar access point to their content and collections available anytime, anywhere. It also adds functionality that has been in high demand from users—social software, citation management, and tagging.

ELECTRONIC BOOKS

In the mid-1980s, the OCLC Office of Research had experimented with electronic books with EIDOS, the Electronic Information Delivery Online System. With the envisioned system, a user could search for a document and browse tables of contents and index pages and, if desired, request the actual text. Staff developed a prototype system, but it did not go into production. In the early 1990s, OCLC, with the American Association for the Advancement of Science, launched the world's first peer-reviewed medical journal, the Online Journal of Current Clinical Trials. OCLC also experimented with different technological approaches to electronic journals until settling on the current ECO model in 1997. Thus, OCLC was no stranger to electronic books and journals when the technology of the World Wide Web made such electronic publications practicable.

In 2002, OCLC acquired the assets of NetLibrary, a provider of electronic books and textbooks. The NetLibrary division provides electronic book content and tools to libraries. NetLibrary's collection contains more than 171,000 titles from 400 publishers, with 90% of new, incoming content published within the last 3 years. The collection includes 7000 eAudiobooks. OCLC MARC

records are included with all NetLibrary eBook and eAudiobook purchases, and holdings are automatically set in WorldCat for member libraries. The multilingual interface is available in Chinese, Dutch, English, French, German, Japanese, Korean, Spanish, and Thai.

DIGITAL COLLECTION SERVICES

In 2003, OCLC began making available CONTENTdm, a software package that facilitates WorldCat access to photos, graphics, and other objects in digitized special collections of libraries and other cultural heritage institutions. In 2006, OCLC acquired DiMeMa (Digital Media Management), the organization that developed and supports CONTENTdm software, which was distributed by OCLC and used by more than 450 institutions to manage their digital collections. In 2008, OCLC added Unicode support to CONTENTdm, thereby extending the software's application in the United States and throughout the world to organizations with primary source materials in many languages. OCLC is now building the OCLC Digital Repository, which will integrate CONTENTdm collections with WorldCat. The metadata for some 100,000 items has already been harvested from 105 organizations and is already in WorldCat.

The DLF/OCLC Registry of Digital Preservation Masters, introduced in 2004, helps libraries build a central, shared registry of digital formats that all participating institutions may one day contribute to and use. By accessing the registry, a library can identify items already digitized and make informed decisions about what items they need to digitize, thereby reducing duplication of effort.

The OCLC Digital Archive provides long-term access and preservation for digital collections. Libraries can share their collections with the world or limit access for their own administrative purposes. Objects can be added one-at-a-time or in batches in a variety of formats. The Digital Archive follows the Reference Model for an Open Archival Information System, which has been adopted as an ISO standard. Dissemination Information Packages from the Digital Archive conform to the Metadata Encoding and Transmission Standard.

Web Harvester, introduced in 2008, allows users of Connexion and CONTENTdm to capture Web-based documents and Web sites from the live Web and manage the collected content as part of their overall digital collection management program.

OCLC also provides high-quality preservation microfilming and digital scanning services for libraries, operates preservation microfilming and digital scanning services for libraries, archives, historical societies, and museums. OCLC has digitized the microfilmed papers of George Washington, Thomas Jefferson, and Abraham Lincoln for the American Memory Project of the Library of Congress. OCLC operates preservation centers in the United

States in Bethlehem, Pennsylvania; Lacey, Washington; and Richmond, Virginia; and in Winnipeg, Manitoba, Canada.

INTEGRATED LIBRARY SYSTEMS

With the merger with Pica BV in the Netherlands in 1999 and the formation of OCLC EMEA, OCLC reentered the local systems business. Pica was a well-established local systems provider, primarily in Europe with its LBS and CBS systems. LBS is an integrated local library management system that supports acquisitions, cataloging, and circulation. The CBS (Central Library System) provides the infrastructure for the creation and management of union catalogs and tools for regional interlibrary loan. There are CBS installations at the Royal Library of the Netherlands, the German National Library, and the National Library of Australia, and at ABES (Agence bibliographique de l'enseignement supérieur) in France, to name a few.

OCLC EMEA also develops and maintains three other library management systems acquired through acquisitions. The OLIB (originally developed by Fretwell Downing Informatics) library management system is installed in about 250 organizations worldwide. In 2008, OCLC EMEA completed a 5-year project to create new public catalog site for the U.S. National Archives and Records Administration based on OLIB. The SunRise library system (originally developed by Sisis) is installed in more than 150 libraries, primarily in Germany, Switzerland, and the Netherlands; the Bavarian State Library is a SunRise user. The Amlib system has some 500 installations in Australia, Africa, and the United States.

OCLC's long-term strategy for the ILS is to create an infrastructure to deliver a large-scale, network-based workflow solution to manage library business processes. The design of the future library management environment will comprise a number of important aspects. It will be an evolutionary process, with new service implemented in a building block process that will eventually become a unified solution. The new services can also be integrated into a library's existing infrastructure and current library management system. The notion is to preserve the functionality of the ILS, but at the same time enhance it by placing it in a network environment, and extending it to manage print, licensed, and digitized material with one solution.

OCLC PROGRAMS AND RESEARCH

On July 1, 2006, OCLC combined operations with RLG, a nonprofit organization of over 150 research libraries, archives, museums, and other cultural memory institutions. By the end of 2007, RLG's services in online cataloging, resource sharing, and digitization/imaging had been integrated with OCLC's. RLG's program initiatives

are being continued as RLG-Programs, a new division of OCLC Research. This unit, based in San Mateo, California, combines RLG's successful tradition of identifying issues and building consensus among research institutions with OCLC's research capacities and robust prototyping capabilities. The combined memberships represent a critical mass of libraries, museums, archives, and other cultural heritage institutions.

OCLC Research staff have developed the following work agenda:

- Supporting new modes of research, teaching, and learning.
- Managing the collective collection of the cooperative.
- Renovating descriptive and organizing practices.
- Modeling new service infrastructures.
- Participating in architecture and standards activities.
- Measuring and assessing end-user behaviors.

The Office of Research, established by OCLC Founder Frederick G. Kilgour in 1978, is one of the world's leading centers devoted exclusively to the challenges facing libraries in a rapidly changing environment. The mission of OCLC Research is to expand knowledge that advances OCLC's public purposes of furthering access to the world's information and reducing library costs. This mission is achieved through the integration of computer, library, and information sciences into research activities including experimentation, prototyping, standardization advancements, studies, and research collaborations. Main areas of research include content management, interoperability, knowledge organization, system and service architecture, and collection and user analysis.

OCLC Research also provides programs that benefit the larger library community. The OCLC/ALISE Library and Information Science Research Grant Program funds research projects by full-time academic faculty in schools of library and information science. The Visiting Scholar program brings experienced professionals to OCLC to work with staff, facilities, and data resources. The Distinguished Seminar Series brings distinguished information professionals to OCLC to discuss their research activities.

OCLC Research develops and provides source code free of charge to the library community for use and further development. OAICat and OAIHarvester are OCLC open-source software programs that implement OAI protocols for data storage and harvesting in support of institutional repositories. DSpace, the open-source repository software created by MIT, uses OAICat to support its OAI (Open Archives Initiative) capability. OCLC Research has also released an algorithm that provides instructions for implementing Functional Requirements for Bibliographic Records on bibliographic databases.

In 2008, OCLC Research staff engaged in variety of projects, including studying the information behaviors of college students. They were also closely involved in

launching the WorldCat API and Developers Network, creating a WorldCat widget for use in Facebook and other social Web sites and developing a service that makes different metadata standards interoperable. They also contributed to the enhancement of OCLC's terminology-based services, the release of a production version of WorldCat Identities, the testing of the Registry of Copyright Evidence and an examination of circulation data from libraries that are members of the OhioLINK consortium. Also in 2008, OCLC Research opened an office at the University of St. Andrews in Scotland to better serve the needs of research libraries and other cultural heritage institutions in Europe.

ADVOCATE FOR LIBRARIES

Libraries have been increasingly urging OCLC to become more active as an advocate for libraries. OCLC pursues this role in a variety of ways. OCLC researchers serve as advocates for libraries in the development of standards. For example, OCLC researchers are active in the Dublin Core Metadata Initiative (see above). OCLC officers and senior managers are involved in national and international professional activities in the library and information community in such groups as the OAI Steering Committee, the Digital Library Federation Steering Committee, the JISC/FAIR (Focus on Access to Institutional Resources—United Kingdom), ALA's Library Business Alliance, NISO's Board of Trustees and Standards Development Committee, and the IFLA Standing Committee on Cataloging.

Another advocacy effort is the Jay Jordan IFLA/OCLC Early Career Development Program, which provides early career development and continuing education for library and information science professionals from countries with developing economies. On an annual basis, up to six individuals, including a theological librarian, are selected for participation in this intensive 5-week Fellowship program. Four weeks are based at OCLC's headquarters in Dublin, Ohio, United States; 1 week is based at OCLC in Leiden, Netherlands. The program gives Fellows opportunities to meet with leading information practitioners, visit libraries, and explore topics including information technologies, library operations and management, and global cooperative librarianship. The Fellows visit selected North American and European libraries, cultural heritage institutions, and library organizations. The Fellows also observe OCLC's governance structure in action, gaining insight into issues affecting the global library cooperative. Fellows give presentations about their home countries and libraries, meet leading information professionals, and discuss real-world solutions to the challenges facing libraries today. The Fellows translate their learning and experiences into specific professional development plans that guide their continued growth as well as their personal contributions to their home institutions and country of

origin. Since the program began in 2001, there have been fellows from Brazil, China, Colombia, Georgia, Ghana, India, Indonesia, Jamaica, Kenya, South Korea, Malawi, Malaysia, Mauritius, Moldova, Morocco, Nepal, Pakistan, Philippines, Rwanda, Serbia, South Africa, Sri Lanka, Trinidad and Tobago, Turkey, Uganda, and Vietnam.

In 2009, OCLC launched the OCLC Minority Librarian Fellowship program designed to provide a unique opportunity for aspiring library professionals from historically under-represented groups. The Fellowship program offers an opportunity to be part of the world's leading library cooperative. The 12-month program offers the selected Fellow two, three-month assignments within specific divisions of OCLC, and one six-month assignment with a specific operating unit within the OCLC organization.

OCLC also develops studies and other information sources that OCLC members can use in their planning and, indeed, in their own advocacy activities. Here is a sample of recent reports.

- "Five-Year Information Format Trends" outlines trends in popular and scholarly materials, digitization projects, and Web resources.
- "Libraries: How They Stack Up" compares library economics and activities to other sectors, professions, and destinations in the worldwide economy.
- "OCLC Library Training and Education Market Needs Assessment Study" produced in conjunction with the Members Council Task Force on OCLC's role in staff development.
- "Libraries and the Enhancement of E-learning" is a white paper issued in 2003 by the OCLC E-Learning Task Force to help frame discussions as to what roles libraries and the OCLC cooperative might play in e-learning.
- "Perceptions of Libraries and Information Resources: A Report to the OCLC Membership" (2005).
- "Sharing, Privacy, and Trust in Our Networked World" (2007).

In 2004, OCLC issued "The 2003 OCLC Environmental Scan: Pattern Recognition." This report to the OCLC membership identified trends that are affecting libraries, museums, and archives in five landscapes: social, economic, technology, research and learning, and library. The *Scan* was based on interviews with 100 information professionals and a review of 300 relevant articles and papers. The report has been well received by OCLC members, some of whom were using it for their own strategic planning efforts. In 2004, the Association of Library Collections and Technical Services, a division of the American Library Association, awarded the authors of the *Scan* a Presidential Citation.

In 2008, OCLC published *From Awareness to Funding: A Study of Library Support in America*. Using a \$1.2 million grant from the Bill & Melinda Gates

Foundation, OCLC partnered with the Leo Burnett marketing agency to conduct research about library funding, and to evaluate the potential of a large-scale library marketing and advocacy campaign to increase awareness of the library's role in the community.

WEBJUNCTION

Started in 2003 with a \$9.2 million grant from the Bill and Melinda Gates Foundation, WebJunction has become a thriving online community of library staff that supports peer-to-peer sharing through online discussions and distributed content publishing. There are over 40,000 registered members and 90,000 unique monthly visitors. There are 15 community partners, most of them state libraries that operate customized versions of WebJunction. The site also hosts 700 online courses for continuing education and 17 custom learning communities for library staff that are sponsored by library service organizations. In 2009, WebJunction launched learning communities for the Research Learning Group, ILLiad (resource sharing) and for library staff outside the United States.

WEAVING LIBRARIES INTO THE WEB: OPEN WORLDCAT

In 2003, OCLC launched the Open WorldCat pilot program to determine the feasibility of providing new services that would integrate the collections of OCLC member libraries into heavily used Web sites. The notion was to make it easy for a person who is looking for information via a search engine to end up finding it in a nearby library. To do this, OCLC would make WorldCat records directly available to the general public for the first time via the Web. Heretofore, WorldCat had been available only through participating libraries.

OCLC began the pilot after extensive consultations with the Board of Trustees, Members Council, regional service providers, and member libraries. The consensus was that it was something the cooperative had to try since numerous studies had indicated that people were turning increasingly to the Web first for their information needs, often ignoring libraries when doing research. The pilot offered the possibility of raising the visibility of libraries on the Web.

In the first phase, users could access links to Open WorldCat through selected Web sites, including Alibris, Abebooks, Antiquarian Booksellers Association of America, BookPage, and HCI Bibliography. In the second phase, 2 million records from WorldCat were made available on search engines, such as Google and Yahoo! Search, with links to the Web-based catalogs of 12,000 academic, public and school libraries participating in OCLC.

In 2005, Open WorldCat became an ongoing program, making bibliographic records of library-owned materials in WorldCat visible and accessible to Web users through popular search engines such as Google, Yahoo! and Ask.com. OCLC has also made it easier to get to member libraries' catalogs by adding always-there access to Open WorldCat from toolbars on FireFox, Google, and Yahoo! Another feature enables users in the United States to buy books online that they find in Open WorldCat; they can then donate a portion of the sale proceeds to the Open WorldCat library of their choice.

WORLDCAT.ORG

On August 8, 2006, OCLC introduced the WorldCat.org Web site. It offers a search box that people can download and use to search all the records and location listings in WorldCat. For the first time, collections in OCLC member libraries became visible on the Internet to people everywhere. This was one of the signal achievements in the history of the OCLC cooperative, testifying not only to the vision of OCLC's founder Frederick G. Kilgour, but to the perseverance and hard work of catalogers and librarians who have built WorldCat record by record since 1971.

By reaching into the working and learning patterns of today's information consumers, Open WorldCat raises the visibility of libraries and other cultural heritage institutions on the Web. It enables information seekers to guide themselves to quality information contained in libraries in an increasingly seamless fashion. It gives users knowledge management tools that enhance their use of the library, both for traditional collections and, increasingly, for digitized special collections.

WORLDCAT LOCAL

In 2008, OCLC introduced WorldCat Local, a compelling user environment that provides a single interface to the collections of a library. It interoperates with locally maintained services such as circulation, resource sharing and resolution to full text to create an integrated experience for library users. WorldCat Local searches the entire WorldCat.org database and presents local and group library holdings at the top of the results list, as well as ownership details for WorldCat libraries outside the local library and consortium.

With the implementation of WorldCat Local, OCLC began providing a local connection to cloud computing. It is a service provided to the library across the Internet that eliminates costs to the library for hosting, operating, and maintaining software. WorldCat Local is "activatable," which means that library staff configure the service from their library using their library's policies. This configuration is done using an online questionnaire that ideally

requires the involvement of staff from both public services and technical services.

WEB SERVICES

Web services enable applications to interconnect over the Web through machine-to-machine interfaces. They cover a wide range of activities that let people tap into computing power on the Web.

In addition to WorldCat.org, WorldCat Local and the WorldCat Identities mentioned above, OCLC has also introduced other Web services in the past 5 years. The xISBN service, developed by OCLC Research, supplies International Standard Book Numbers (ISBNs) associated with an individual intellectual work, based on information in the WorldCat database. It finds all related editions of a book, including paperback, hardback, audiobook, foreign and out-of-print. Easily incorporated into library catalogs, the service is available free to OCLC cataloging members and for a fee to others.

The WorldCat Registry is a Web service, which enables a library to manage its institutional identity more efficiently. On a secure Web platform, a library can create and maintain a single profile that includes information of use to the library's consortium members, technology vendors, eContent providers, funding agencies, and other partners. This access enables the library to automate routine tasks such as activation of a new subscription service or renewal of an existing one. In 2008, the Registry included more than 120,000 institution records for OCLC and non-OCLC members.

In 2008, OCLC established the WorldCat Developer's Network by inviting a small group of developers from OCLC cataloging institutions in North America and Europe to use the WorldCat API (Applications Programming Interface) to build applications that would guide people from the Web to library services. These developers could then link WorldCat information to Internet applications as well as presentations, blogs, and e-mails. This shared development will enhance the creativity and usage of WorldCat.

GOOGLE AND OCLC

In 2008, OCLC and Google agreed to exchange data to will facilitate the discovery of library collections through Google search services. OCLC member libraries participating in the Google Book SearchTM program, which makes the full text of more than 1 million books searchable, may share their WorldCat-derived MARC records with Google to better facilitate discovery of library collections through Google. Google will link from Google Book Search to WorldCat.org, which will drive traffic to library OPACs and other library services. Google will share data and links to digitized books with OCLC, which will make it possible for OCLC to represent the digitized

Fig. 4 The OCLC cooperative: 2008.
Source: OCLC.

collections of OCLC member libraries in WorldCat. OCLC began online operations in 1971 with 54 academic libraries in Ohio. In 2008, more than 69,000 libraries in 112 countries had a unique holding symbol in the WorldCat database and were participating in some way in the OCLC global cooperative (Fig. 4).

U.S. ACTIVITY

For the year ended June 30, 2008, revenues from U.S. operations were \$190.2 million, or 77.2% of total revenues of \$246.4 million. Here are a few highlights of U.S. activities in fiscal 2008.

- University of Washington Libraries enters 100 millionth bibliographic record in WorldCat on April 1, 2008.
- State Library of Ohio begins using WorldCat Local production version.
- Mellon Foundation awards OCLC \$145,000 grant to conduct data exchange study with seven RLG Programs art museum partners.
- Orbis Cascade Alliance and OCLC are working together to migrate the Alliance's Summit union catalog of 38 libraries to a consortial borrowing solution.

ACTIVITY OUTSIDE THE UNITED STATES

Revenues from operations outside the United States in fiscal 2008 were \$56.2 million, or 22.8% of total revenues. Here are some highlights of OCLC activities outside the United States for fiscal 2008 (year ended June 30, 2008).

OCLC ASIA PACIFIC

- OCLC Beijing Representative Office established on July 25, 2007.
- National Library of China to load Chinese records into WorldCat.
- National Central Library, Taiwan to load Chinese records into WorldCat.
- Completed loading of the National Union Catalog of Australia into WorldCat.
- Completed loading of the National Union Catalog of New Zealand into WorldCat.

OCLC CANADA

- University of Manitoba to use OCLC Canada LTS for outsourced cataloging.
- Edmonton Public Library to use OCLC Canada LTS for outsourced cataloging of Chinese language materials.
- Twelve new governing members to catalog on OCLC.
- Six new Canadian publishers to contribute eBooks to the NetLibrary collection.
- Presented the first OCLC Symposium in Canada during Canadian Library Association annual conference on Social Networking and Web 2.0.

OCLC LATIN AMERICAN AND THE CARIBBEAN

- More than 48,000 records from RedALyc (scientific journals from Latin America, Spain, and Portugal)

were loaded into WorldCat with access to article level full text.

- The National Library and Information System Authority of Trinidad and Tobago became the first national library in the Americas offering the QuestionPoint service to provide virtual reference services.
- The Pedro Henriquez Ureña National Library in the Dominican Republic joined OCLC as a cataloging member.
- More than 470,000 records of scientific material related to agriculture and animal research from Embrapa (Brazil) were loaded into WorldCat.
- State of Jalisco Public Library system (Mexico) began using NetLibrary eBooks.

OCLC EUROPE, THE MIDDLE EAST AND AFRICA

- Signed an agreement with the UKB (Association of Dutch University Libraries, the Royal Library, and the Library of the Royal Academy of Sciences) in the Netherlands to continue managing the Dutch national information infrastructure.
- Loaded into WorldCat bibliographic files from the National Library of Sweden, Swiss National Library, Hebils, and Bavarian State Library.

- Migrated LinkUK data to UnityUK creating a single national union catalog in the United Kingdom.
- Introduced the Netlibrary platform for distribution of Dutch eBooks to Dutch public libraries.

FUTURE DIRECTIONS

Since 1971, OCLC has provided libraries with \$3.7 billion in products and services. WorldCat is in the workflows of most parts of the library, including acquisitions, cataloging, reference, resource sharing, and circulation. OCLC products and services have not only been at low cost, but have saved libraries millions of dollars. Clearly, the OCLC cooperative has worked well for 37 years. Going forward, OCLC will provide local, group, and global nodes that work together seamlessly and symbiotically as it continues to pursue its mission of furthering access to the world's information and reducing the rate of rise of library costs.

Older Adults' Information: Needs and Behavior

Kirsty Williamson

*Caulfield School of IT, Monash University, Caulfield, Victoria, Australia and
School of Information Studies, Charles Sturt University, Wagga Wagga, NSW, Australia*

Terry Asla

Senior Lifestyles Researcher, Seattle, U.S.A.

Abstract

The proportion of older adults, usually defined as aged 60 or 65 and over, is expanding rapidly in the populations of many countries of the world, leading to the expectation that they should have growing importance from a research perspective. It is therefore surprising that there have been few substantial studies of the information needs and behaviors of this group, apart from research of which the principal focus is library services. This entry discusses the major studies that have been undertaken on the topic, mentioning library studies only where relevant. Library services are not part of the purview and are dealt with only briefly. The introduction discusses definitions of "older adults," why there is an imperative for studying this large, diverse group and the role played by research with a library focus. The entry then examines what is known about human information behavior (HIB) in the context of everyday life information focusing particularly on information needs, the sources used to meet those needs and the role of residential context (for the very old and frail) where this is relevant. Where possible, the findings are discussed in terms of the three age groups into which older adults are sometimes divided: the young aged (60–74), the old–old (75–84), and the very old (85+). Recently, the concept of the Fourth Age has been introduced into the HIB field. The Fourth Age describes people who have multiple disabilities and are usually in the last stage of their lives. The physical, cognitive, and social losses of the Fourth Age have significant impact on HIB. Since computers and the Internet have now become such important tools in the information-seeking process, the next section of the entry focuses on these topics. The conclusion is that further research is needed, that people in the wide age span from 60 to 65 plus should not be treated as homogeneous in their needs, and that the Internet be included in future research but that it should be examined in the context of other sources of everyday life information.

INTRODUCTION

The goal of this entry is to explore what we know about the information needs and behaviors of older adults. To do this, we need to begin by defining the group at the center of the discussion, involving as it does a very large age span that needs to be further subdivided for meaningful conclusions to be reached.

Defining "Old"

The simplest, most comparable, and widely used definition of "old" is chronological age (p. 9),^[1] also referred to as calendar age. In the United States, because the Social Security Act of 1935 was viewed as "old-age security legislation" intended for people aged 65 and older (p. 184, 200),^[2] this age became, officially and in common parlance, the time when old age was said to begin (p. 258).^[3] The age of 60 plus is the definition of "old age" accepted by most developed countries, though there is no UN standard numerical criterion.^[4] It should be noted that the age at which citizens are eligible for the

old-age pension is set to rise over the next few years to 67 in countries such as United States, the United Kingdom, and Australia, the adjustment considered necessary because of the increased life span now occurring.^[5–7]

Because of the disparate physical and cognitive differences noted among adults aged 60 and older, gerontologists early on divided the aged into three groups commonly designated as the young aged (60–74 years), the old–old (75–84), and the very old or "oldest old" (85+). In the field of library and information science, most researchers have continued to treat older people as one group, aged over 60 or 65. There have been exceptions, which include Turock^[9] and Wooliscroft,^[10] who, in their work about older people and libraries, have found the three subgroups useful. Today, the "very old" group is often referred to as the "oldest old"^[11] the designation that Asla et al.^[12] used in their 2006 article in *Library and Information Research*.

Even the division of the aged into three groups did not solve problems for researchers who found a wide disparity in abilities among members of each of the specific groups. Consequently, gerontologists developed Fourth Ages

theory, with the Fourth Age referring to that time in life described as “the disability zone” (p. 31).^[8] Members of the Fourth Age are identified by specific, measurable physical, cognitive, and social losses, which have significant impact on their lives and also on HIB: vision, hearing, cognition, chronic illnesses, and mobility. Thus researchers who employ the Fourth Age definition “are assured of studying a homogeneous group of individuals approaching the end of life.”^[13] Recently, the concept of the Fourth Age, describing people in the “disability zone” and usually in the last stage of their lives, was introduced into the HIB field by Asla,^[13,14] whose study was undertaken in two retirement communities in the United States.

In this entry, we review literature where “older adults” are regarded as aged at least 60 years, but we also describe what is known about how baby boomers might bring changes in HIB as they reach the age of 60 plus as the oldest ones have already done. Where possible, the sub-age groups, mentioned earlier, will be discussed in relation to key topics of discussion.

The Imperative for Studying Older Age Groups

Of crucial importance in any consideration of the information needs and behavior of older people is the effect of the very large generation labeled as “baby boomers” (persons born between 1946 and 1964). While the youngest baby boomers have yet to turn 60, there is growing interest in the future impact on the public library of the library and HIB needs of this cohort.^[15] A key argument for focusing research attention on older age groups stems from the fact that the proportion of older people is increasing and becoming quite significant. The phenomenon of the burgeoning older population is well known in the developed world. In the United States, the number of people aged 65 and over at the time of the 2010 Census was more than 40 million or 13% of the total population. Between 2000 and 2010, the population 65 years and over increased at a faster rate (15.1%) than the total US population (9.7%).^[16] Between 2010 and 2050, the US population aged 65 and over is projected to grow to 88.5 million, with the baby boomers, who began turning 65 in 2011, being largely responsible for this increase. By 2030, when all of the baby boomers will have turned 65, the percentage of the US population aged 65 and over will be 19% (compared to 13% in 2010) and will rise slightly again by 2050.^[17] In 2030, when the last baby boomer turns 65, the demographic landscape will have changed significantly. One of every five US citizens—about 72 million people—will be an older adult.^[18] The number of people in the oldest age group (85+) is also projected to rise dramatically from 5.8 million in 2010 to 8.7 million in 2030 and 19 million in 2050 (4.3% of the US population, up from 2.3% in 2030), again because of the effect of the baby boomers.^[17]

In Australia, where the lead author of this entry lives and where a major study of the information-seeking behavior of the older population was undertaken, there are comparable statistics. At the time of the 2011 Census, 3.1 million people were aged 65 or over, accounting for about one in seven Australians.^[19] Between 1971 and 2011, the proportion of Australia’s older people increased from 8.3% to 14%. The projected increases are to 22% in 2061 and to 25% in 2101. For those aged 85 years and over (the age group most apt to be in or entering the Fourth Age), numbers had more than tripled, to 420,300 between 1971 and 2011, with proportions increasing from 0.5% to 2% of the population over that period. This group is projected to grow rapidly, to 5% by 2061 and to 6% by 2101.^[20]

Like Australia and the United States, all of the world’s developed nations face the same problem of rapidly aging populations. Given such large increases in numbers and population percentages, it is imperative that there be an increase in research in all fields, including in the “information” arena.

Library-Based Research

Starting with the 1975 White House Conference on Aging, there were a large number of studies and discussions focusing on the provision of library services to older people, some emanating from the American Library Association (ALA). In recent years, the number of such studies has declined dramatically despite the increased aging of the population, as noted by Perry.^[21] The White House Conferences on Aging, held every 10 years, involve events sponsored by the ALA, the latest in 2005 titled “Libraries, Lifelong Learning, Information and Older Adults.”^[22] The ALA has also provided guidelines for library services to older adults.^[23] An important resource, the database AgeLine, produced by the American Association of Retired Persons and available on EBSCO Host, is a very useful resource provided in some public libraries. Decker provides a worthwhile discussion of baby boomers in relation to the US public library system, focusing on facilities, services, technology, and library staff.^[24] Her article draws on several papers presented at a conference in NSW (Australia) in 2009: “Next chapters: public libraries for older adults in Australia and New Zealand” and published in the journal, *Australasian Public Libraries and Information Services*. The papers cover a range of needs, services, and age cohorts, including baby boomers.^[25] Earlier library-based research focused primarily on audits of services, programs, and the allocation of library resources for older patrons, for example, Turock and Ip.^[9,26] A recent study using this approach was undertaken by Perry.^[21] Unfortunately, most of these studies treated older users as a homogeneous group aged about 65 years and older. Since library services are not central to this entry, studies where libraries are the focus are not discussed further unless they shed significant light on needs and behaviors associated with everyday life information.

Everyday Life Information Seeking

What do we know about the needs of older adults for information for everyday life and how these needs are met? There are few projects that have explored this topic in any depth. We know that "health" is an important topic for older people and that there have been a number of studies of older people in relation to health information.^[27–29] Other studies have focused on online access for older people and people with disabilities, with "information" being an obvious concomitant.^[30] Other examples are provided later.

Two of the major studies of information seeking, published during the 1990s, took different approaches to the topic. Chatman^[31,32] studied the information world of 55 women, who lived alone in a retirement community in a southern US city and whose average age was 82 years (age range 68–100). Using what she termed "social network theory" and an ethnographic approach during the 2-year study, she explored the women's information and recreational needs, as well as the sources routinely used in response to those needs. For her, the term "social network" referred to the interpersonal communications that assist people in meeting problems and her focus was on the role of personal networks, for example, family, friends, neighbors, or professionals, in meeting the needs of older women. Williamson^[33,34] used an ecological framework, taking into account the physical and social environments of her participants, to explore the information-seeking behavior of her 202 older adults, aged 60 and over. The sample included 146 persons who were aged 60–74 (the young-aged), 44 persons aged 75–84 (the old-old), and 12 individuals aged 85 and older (the very old). The data were collected by interview (three with each participant) in both city and rural areas.

A further major multidisciplinary study employing the Fourth Age rather than chronological age was recently completed by Asla.^[13,14] Significant findings about the HIB of this specific group emerged from this study, which was undertaken in two retirement communities in the Midwestern US.

Information Needs

Chatman identified six broad areas where older people needed help: 1) *dealing with loss*, including loss of material possessions, friends and family, familiar and known surroundings, health, and control over one's life events; 2) *death and dying*, pertaining not only to one's own death but to the death of loved ones; 3) *the aging process*, the first dimension concerned with maintaining a high level of involvement in social and personal interests, known to be important in successful aging; the second concerned with sexism due to the unequal standards applied to men and women with regard to physical attractiveness as they age; 4) *uncertainty about the future*, focusing on worries such as "being a burden, going to a nursing home, dying, poor

health, or financial concerns"; 5) *fear of crime*, particularly affecting women; and 6) *loneliness*, again particularly acute for women who are four times as likely to be widowed as men. Chatman confirmed these broad areas in her own research but also found that the women had significant needs in such areas "as health, financial problems, and general news about activities in which one could become involved" (p. 78).^[32]

Williamson's approach^[33,34] was to build on earlier projects about information-seeking behavior of the broader community, as well as studies of older people from other fields, for example, Tinker et al.^[35] from gerontology and Nussbaum et al.^[36] from communication. This enabled comparison with these studies. As with other studies of the information needs of older people, health was the number one topic for the sample as a whole. The second topic of concern was income and finance, and recreation was the third. These topics have all emerged as important in other studies. Other topics, in descending order of importance, included government, consumer, housing and accommodation, retirement benefits, crime and safety, environment, pharmaceuticals, holidays, legal, transportation, family and personal, education, employment, services (e.g., meals on wheels), and volunteer opportunities. Voluntary work was found to be an important topic in phase 2 of Wicks' North American study, the phase involving the younger of his two cohorts who were not living in residential communities.^[37] This topic is likely to be a significant interest of baby boomers who are now beginning to be part of the "young aged" group.

Asla's study^[13,14] findings, regarding the daily living information needs of his Fourth Age cohort, were similar to those of Williamson. The first of the two exceptions was "adaptive devices" for which about 80% of participants expressed a need for information, mostly for vision and hearing losses. The second was "safe mental challenges," noncompetitive activities such as matching wits with television game shows like *Wheel of Fortune* (these were encompassed, in a more minor way, in Williamson's "recreation" category).

Research focusing on the likely library needs of baby boomers as they retire from their full-time occupations suggests that some of their information needs, right through the stages of their older age, are likely to be different from the past^[10,38–40] especially given the better health they will experience and their increased life expectancies. The literature indicates that additional important information needs will be connected to issues of successful retirement and the challenges of aging well, estate planning, travel, genealogy, and employment planning that will be different from the past in that baby boomers may wish to continue working, although in a more flexible capacity than in the past, or may have to work to sustain the lifestyles they want. The latter scenario is more likely in the case of the younger boomers who are likely to face more financial hardship than the older cohort.^[41] Projected

worker shortages mean that governments are now encouraging people to work longer.

What do we know about the differences in information needs of the three groups within the broad older cohort? The Williamson study found that the younger aged had a need for more information topics and that the range of information needs diminished as people became part of the "old-old" or the "very old" cohorts. The exceptions were the topics health, income, recreation, and pharmaceuticals, where the needs remained strong as people age. Asla, too, found that information needs declined, although this decline could sometimes be slowed by outside intervention, such as providing people in the Fourth Age with opportunities designed to help them maintain their role identities. For example, in one of the retirement communities, residents were given roles such as "librarian" or "artist."

Information Sources

Given that social networks underpinned Chatman's study, she undertook a deep exploration of the interpersonal relationships and support provided to study participants. The residential setting was crucial here as it meant that there were many "neighbors."

Although Chatman found some use of professionals (e.g., doctors, lawyers) as sources of information, she did not find as strong dependence on professionals as Williamson did among the old-old and very old (but not the young aged). Chatman^[31] found the mass media to be important in mediating access to the larger world for those who were now isolated from it. The most frequently used medium was television, followed by books, newspapers, radio, and magazines. Wicks^[37] and Williamson^[33,34] also found that the media were very important, with newspapers, television, printed information, and radio all being in the top six most used sources in the Williamson study. A recent study has focused on media use by older adults.^[38] Both Chatman and Williamson found that there was considerable use of libraries that, in Chatman's case, occurred through the outreach service offered to the retirement community.

In the Williamson study, the list of six sources that were very frequently used in information seeking or acquisition, regardless of topic, included (along with the media sources) family members at number 1, and friends at number 3. Nevertheless, there was a difference in source use according to age, which to some extent mirrored the "information needs" picture in that the young aged used more sources, particularly media sources, than the "old-old" or the "very old" cohorts. The two oldest groups set particular store by medical professionals and paraprofessionals for meeting key information needs and also were more reliant on family members and, to a lesser extent, on friends. As Chatman found, "friends" from earlier life stages were not a key information source for some of the very old since members of this group were becoming

increasingly isolated due to failing health and the loss of friends through death or other circumstances. Also, they sometimes appeared to be unable to sustain the effort needed to maintain friendships. Asla,^[13,14] whose study like Chatman's was undertaken in the small world of retirement communities, found that key information sources were caregivers, usually one specific family member or an individual who was "like family" (including retirement community staff members). Other key informants were intimate social networks, including other family members and close friends. Other sources included wider social networks; mass media; small world sources such as resident meetings and information grounds; and outside professional and institutional sources. Asla also found proxy information seekers (i.e., people who sought information on behalf of those needing the information) became increasingly important, as also demonstrated by Pálsdóttir's Icelandic study of frail elderly still living in their own homes.^[43]

Information Literacy of the Very Old (the Fourth Age)

This is a topic that has been discussed in the literature, to a limited extent. Williamson and Asla^[44] discussed issues of whether commonly discussed definitions of information literacy are appropriate for people in the Fourth Age and thus whether general definitions of information may be found wanting for this group. The multiple disabilities experienced by people in the Fourth Age are likely to have a major impact on information literacy, which is usually strongly linked to textual information. Williamson and Asla postulated that the first and foremost element needed for sustaining information literacy in this last stage of life is maintaining a healthy relational system, thus facilitating communication. Another component is attempting the "compression of information illiteracy" where the focus is to help people maintain the information literacy skills, which they have developed earlier in their lives. Asla explores these issues in his thesis.^[14]

Residential Communities

The effect of retirement communities on information-seeking behavior was important to the Chatman study,^[31,32] the first phase of the Wicks' study^[45] and to Asla's study of the Fourth Age.^[13,14] The sample for Wicks study consisted of 15 people residing in one of two residences for seniors, the majority of whom were in the "oldest-old" age group (mean age was 83.6). Wicks found that participants relied largely on meetings to find out what was happening in their residential setting. Wicks concluded that "information flow within seniors' accommodation is crucial and becomes even more important as age and functional abilities decline" (p. 23). He discussed the role of staff in this and called for research on information dissemination in residential communities. Asla

confirmed these findings about the importance of information provision within the small world. He also found that the opportunity for his participants to do internal voluntary work related to their personal role identities was important. Especially in one of Asla's two retirement communities, management consciously tailored volunteer opportunities to residents' interests. This challenges the conclusion of Wicks who found that lifelong role identity played no significant part in the information behavior of his retirement community participants.

Computers and the Internet

The Internet is making a major difference to the information-seeking behavior of the "young aged" as is made clear in the study of baby boomers by Williamson et al.^[15,25,46] The study was undertaken with baby boomers in 2005–2007, meaning that some of the participants would now be part of the "young aged." There was mainly a continuity of information needs as revealed in the earlier major studies, with health information needs being particularly important. While participants, as before, wanted access to a wide variety of information in as many formats as possible, they were making considerable use of the Internet for a range of information needs. As one technologically savvy participant commented, "apparently there's quite a growing trend towards self-diagnosis [on the Internet]." Another spoke of relying a lot "on electronic media. . . I access electronic databases like Medline to find out about medical issues."

Although the percentage of older people who go online has risen as the technological revolution has proceeded, there are still big differences between younger and older age groups. While, for the first time ever, more than half of Americans aged 65 or older went online in 2012 (59%), they still lagged behind younger Americans in technology adoption (p. 1).^[46] Moreover, Internet use and broadband adoption in this age group each fell off notably starting at approximately age 75. Some 68% of Americans in their early 70s went online in 2012, and 55% had broadband at home. By contrast, Internet adoption fell to 47% and broadband adoption fell to 34% among 75–79 year olds (p. 2). Physical, cognitive, and sensory losses are major impediments for the very old or people in the Fourth Age.^[47] In Australia, 83% of the population went online in 2012–2013, but age group percentages fluctuated from 97% of people aged 15 to 17, to 46% of those who were 65 or over.^[48]

Dickinson and Gregor^[49] found that "technology is frequently presented as a panacea for the support needs of the ageing population" but that research did not support that conclusion. Research shortcomings included "failure to distinguish between the effects of training/support and computer use; misattributing causality; [and] inappropriately generalizing results from a different population" (p. 744). With technology use declining as people become

increasingly old, electronic information delivery is unlikely to meet their needs. While half of Asla's Fourth Age participants used, or had recently used computers and/or the Internet, by the end of the 2-year study, not one participant had been able to independently master, let alone successfully maintain a new computer or Internet skill. As their physical and cognitive health failed, they needed more and more technical support and services, and had to rely more and more heavily on proxy information seekers.^[13,14] Wales^[50] saw the Internet for frail and vulnerable older people (including those in daycare centers and residential homes) as "a person issue before a technology issue." While some may be able, with assistance, to learn Internet skills for themselves, a personal approach is needed because of the physical limitations of the people involved and the unfamiliarity of the technology and its benefits to many older people (p. 41). Even the younger aged may not be satisfied by electronic information delivery alone. A key finding of Wicks' study of nonresidential older people^[37] was that they strongly preferred obtaining information through interpersonal contact and print sources rather than through electronic delivery despite the increasing preference of governments to delivery of information via the Web (p. 20).

There is a large body of literature about computer use in relation to disabilities, much more likely to affect the very old/oldest old and, to a lesser extent, the old-old. The use of assistive technology, such as large print keyboards and enlarged text on screens, can be greatly beneficial and help to prolong Internet use.^[51,52] There is also no shortage of advice in the literature on interface design issues.^[53,54]

There has been some useful research undertaken regarding e-health literacy and collaborative learning.^[55–57] Xie conducted a series of experiments focused on computer-based training, to encourage participants to play a greater role in their health management. The experiments showed improvements in skills and attitudes. Participants reported that their learning had affected their participation in their own health care and provided positive feedback on the intervention.^[57]

Conclusion

To date, there have been few substantial studies of the information needs and behaviors of older adults that have not been limited to a library context. Given the fact that the proportion of older people is increasing and becoming quite significant, at least in the developed world, there is scope for more research to take place. It is important that future research take account of the very wide age span from aged 60 or 65 upward, and that this group is no longer treated as homogeneous in its needs, behaviors, and environmental contexts. It will also be important to include the use of the Internet for information seeking by the older age groups as this area is under-researched at

present, but it is particularly important that it should be examined in the context of other sources of everyday life information. Studies that span all sources of everyday life information are likely to be most fruitful, given the finding of the extensive Williamson study (pre-Internet), confirmed in other literature, that “no one source is able to provide all the information needed by a very diverse older group” (p. 267).^[58] Williamson, the first author of this entry, added that “it is also imperative to consider the likelihood . . . that older people will be slower than other groups to accept computer-based sources of community information.” This prediction of almost 20 years ago is, at this stage, turning out to be correct. With regard to tomorrow’s Fourth Agers—those who have employed computers and the Internet in the workplace—the second author’s research^[14] suggests that the physical, social, and cognitive losses associated with the Fourth Age will make it increasingly difficult to maintain those skills, let alone master new ones. Research into viable outside intervention and support to offset or delay this HIB challenge is badly needed.

One-Person Libraries

Judith A. Siess

Information Bridges International, Inc., Champaign, Illinois, U.S.A.

Abstract

A one-person librarian (OPL) is a person who works in a one-person library. What does that mean? An OPL is the only librarian (or only professional librarian) in a library or information center. The OPL does everything from acquisitions, cataloging, circulation, and reference, even dusting the shelves and vacuuming the carpet, if necessary. It is a situation in which there are no professional peers with whom to share problems and ideas, or to commiserate with when things get tough. The OPL often does not have to go through layers of administration to get approval for purchases or new programs. OPLs know exactly what is going on their libraries: what is being checked out, what questions are being asked, who is using the library, etc. The OPL is often perceived as the “information guru” in the organization—the one to whom everyone comes for answers. Finally, any and all successes (and, of course, failures) of the library are also those of the OPL. They can make of it whatever is in their vision and power.
